now found possible to make a 50 per cent ferro-uranium with less than 5 per cent carbon by mixing steel turnings with the necessary  $U_3O_8$  and coke, together with a considerable quantity of fluorspar. The entire mixture was added slowly to the furnace at the rate of 2 pounds every 5 minutes. The resulting alloy then gave a recovery of 50 to 70 per cent when used as an addition to steel designed to contain 4 to 2 per cent uranium, respectively. Additions for low uranium steels may be made in the ladle; if considerable quantity of the alloy is to be added, however, it must be made in a skimmed furnace within one minute of pouring.

"Ferro-uranium is brittle, has a high density, and when it contains over 20 per cent uranium has a tendency to be pyrophoric, this tendency increasing with the percentage of uranium. A 3 to 5 per cent carbon alloy, with less than 15 per cent uranium, has a dense non-crystalline structure, and is dull gray in color. When the uranium content reaches 18 to 20 per cent, small bright crystals appear; and as the alloy approaches 50 per cent uranium, these crystals become larger, longer, and more distinct. From 18 per cent up, the alloy has a brilliant, flaky fracture. At 18 per cent it is hard to break, but at 50 per cent uranium it breaks easily. With the commercial 50 per cent alloy no graphitic carbon is present if the total carbon is under 5 per cent, but if there is over 5 per cent carbon, this excess carbon is usually graphitic. Any of these alloys has an entirely different appearance if cooled from a white heat in water, this treatment giving it a granular and dirty appearance. If the carbon is less than 1.5 per cent, the alloy has a dense gray appearance and is difficult to break. Under the microscope, the uranium appears to be present as the double carbide of iron and uranium,  $Fe_2C.U_2C_3$ , in a eutectic mixture of iron and carbon.

"Uranium metal with over 90 per cent uranium has a dull black color. It is dense in structure, but powders easily. It is very pyrophoric, and draws a long spark when struck across steel or another piece of uranium metal. Uranium carbide is also pyrophoric, but is more flaky in structure than a mixture of uranium metal and uranium carbide."

## TUESDAY, SEPTEMBER 3

The second day's social affairs planned for the Mining Engineers were sadly marred by wet, misty weather, which rendered impossible the many cañon trips contemplated. Most of the members attending arrived in Colorado Springs on the morning trains, and were served luncheon at the recently completed Broadmoor Hotel, where were established the permanent registration headquarters. Impressive services were held early in the afternoon in memory of the late Dr. James Douglas, brief addresses by Messrs. JENNINGS, MATHEWSON, INGALLS and O'BRIEN recounting his many sterling qualities.

Preceding the technical session were shown moving pictures of the Canadian reconstruction hospitals for wounded soldiers. The inspiring work they are there doing will point the way for us to provide adequate and honorable occupations for our own returned boys. Dr. RICHETTS then exhibited films showing the inter-

esting operations of the Ajo works of the New Cornelia Company, speaking extemporaneously in explanation of the pictures. A joint technical session on Coal and Coke was held with the Rocky Mountain Coal Mining Institute with A. E. CARLTON in the chair, while G. H. CLEVENGER presided over a simultaneous meeting on Ore Dressing and Cyanidation. The evening was enlivened by a reception and dance to visiting members and their guests.

## Technical Session

**Hand-Sorting of Mill Feed.**—A typical sorting plant on Coeur d'Alene ores handles 800 tons of ore between 12 and 4 in., from which 50 tons of shipping ore of about 45 per cent lead and 150 tons of waste is removed at a cost of \$125. Mr. R. S. HANDY, the author, believes that straight crushing and milling is not only cheaper, but is metallurgically more economical and efficient than hand-sorting followed by milling of the residue. The ore could be prepared for milling by crushing at 3 cents per ton, as compared to 16 cents in the sorting plant. The recovery on this rich fraction would be much higher than the average, since the ore does not slime and the jigs get all the coarse galena. Assuming that all the slimes passing the jigs is from this ore and would be lost it would amount to but 50 lb. of lead per day.

If there is no advantage in sorting out shipping product, there must be less advantage in sorting out waste, when the cost is 50 or 60 cents per ton of waste rejected. There is an economical advantage in milling as against hand-sorting that seems to be little considered, which is in the grading of the products. The author presents curves which show a definite economic peak where the various factors of recovery, grade and cost combine to give a maximum net money return to the operator, and concludes that "the crux of the whole matter is, 'What can you do with the hand-sorted product in the mill?' and not, 'What does the mill do on the feed it is getting?'" The only sure test is to run the mill on a hand-sorted product long enough to determine what grade of concentrate and of tailings can be achieved. I am sure a test of this kind would surprise many of the advocates of hand-sorting by demonstrating the enormous economic advantage to be gained by the opposite method of treatment. If any process in the mill produces a higher-grade concentrate than it is practicable to sort out by hand, or if any process in the mill produces a tailing equal in grade to that sorted out by hand, then it is advisable to mill the hand-sorted material."

In the discussion of this paper, Mr. A. STANLEY HILL takes issue with the author, stating that at the Hecla Company's property the ore-sorting plant does 23 per cent of the work at 15 cents per ton of material sent through, whereas it costs 36 cents to mill a ton of ore. To handle the sorted ore a heavy expenditure in mill construction would be necessary. "In the crushing plant no material is obtainable for any purpose other than milling, whereas in the sorting plant we obtain waste suitable for mine filling (an acute problem, as tailings could not be shipped from the mill except at prohibitive rates)." In order to be convincing, Mr. Handy's statement that recrushing and rejigging produces less sliming than occurs in the bed of the jig when bringing

up the grade of the concentrate should be supported by sizing tests and proper analyses.

Mr. W. L. ZEIGLER pointed out that the advantages of hand-sorting depend mainly upon the physical characteristic of the ore in question, especially of the possibility of removing extremely hard gangue, of the chance of hand-separating ore containing minerals with difficulty separated by concentration or which slimes excessively.

CLARENCE A. WRIGHT called attention to the Joplin practice, where the hoisted rock is dumped on a 4- or 5-in. grizzly. Many barren flint boulders are sorted here, the quantity reaching 20 per cent at times, the inclusion of which these operators feel would lower the capacity of the mill and increase operating costs.

Replying to the critics, the author said he thought Mr. Hill had not considered that the large proportion of his milling cost is in the handling of middlings and fine material, which products would hardly be increased by handling the coarse high-grade ore. If Mr. Hill's mill feed consisted of nothing but the material which is sorted, his lead recovery and costs would put the milling world to shame.

**Fine Grinding Plant of the Barnes-King Co.**—In a description of this plant, Mr. J. H. McCORMICK notes that the all-slime treatment was adopted in order to treat ores from several mines differing somewhat in nature. One hundred and fifty tons of ore per day are crushed in coarse breakers, and then ground in slow-speed Chilean mills. "These mills make a remarkable reduction, but leave some fine sand to be slimed in the tube-mills. Repairs are required rather frequently and access to make repairs is difficult, making the mills unpopular with the attendants. Crushing costs, however, compare favorably with other modes of coarse crushing, being, in fact, rather less than those shown by larger plants using ball-mills. An undesirable feature of these mills in a slime plant is that their product is too uniformly fine for regrinding in a pebble-mill without undue consumption of pebbles."

The balance of the paper presents a description of the flow-sheet, together with data as to the metallurgical recoveries and costs. As an instance, Table I is selected:

TABLE I—PRINCIPAL ITEMS IN COST OF MILLING 52,885 (Dry) TONS

|                                     | Total Amount<br>Used | Total<br>Cost | Per Ton   | Cost     |
|-------------------------------------|----------------------|---------------|-----------|----------|
| Lane steel                          | 21,576 lb.           | \$2,596 79    | 0 41 lb.  | \$0 0491 |
| Grinding pebbles                    | 534,000 lb.          | 5,796 85      | 10 10 lb. | 1 096    |
| Cyanide                             | 40,490 lb.           | 13,138 04     | 0 77 lb.  | 2 484    |
| Lime                                | 583,823 lb.          | 3,352 99      | 11 08 lb. | 0 634    |
| Zinc shavings                       | 44,835 lb.           | 9,010 90      | 0 85 lb.  | 1 704    |
| Steam coal                          | 489,000 lb.          | 2,167 35      | 9 25 lb.  | 0 410    |
| Borax glass                         | 4,530 lb.            | 887 09        | 0 08 lb.  | 0 168    |
| Lumber-tailings dam                 | 29,892 ft.           | 777 52        | 56 ft.    | 0 187    |
| Commercial hydrochloric acid        | 7,574 lb.            | 990 16        | 0 14 lb.  | 0 187    |
| Commercial sulphuric acid           | 17,819 lb.           | 488 46        | 0 34 lb.  | 0 092    |
| Fuel oil                            | 1,210 gal.           | 176 98        | 0 02 gal. | 0 0033   |
| Diaphragms No. 4                    | 222                  | 579 80        |           | 0 0110   |

| Elevator buckets 12-in., 10-gal.    |                      |               |           | 0 013    |

**Effect of Oxygen on Precipitation of Metals from Cyanide Solutions.**—Mr. THOMAS B. CROWE'S paper on this subject excited much favorable comment. He became convinced that nascent hydrogen, given off by dissolving zinc, is the real precipitant of gold from cyanide solution; thus while dissolution of the metal is an oxidizing process requiring oxygen for its operation, precipitation is essentially opposite, a reducing process requiring hydrogen. In precipitating solutions

containing dissolved air much of the zinc was wasted because its evolved hydrogen had first to combine with and remove oxygen before getting an opportunity to precipitate zinc.

"Laboratory tests on the application of a vacuum to solution before the addition of zinc-dust confirmed my theory. Large tests were tried, apparatus was designed that would continuously apply a vacuum to solution during its flow to the precipitation presses, and gradually the vacuum system of precipitation worked its way into our mills, with the result that the zinc consumption has been cut in half, which fact is especially gratifying to us during the war period with its prevailing high prices.

"A thorough scrutiny of our former work revealed the fact that, for dissolution purposes on our particular ore, the cyanide solution strength was much higher than was necessary, having been kept high for the sake of good precipitation. In fact, the solution strengths in our mill had been reversed—the strongest solution was the barren; and this being used as a wash on the filters, occasioned high cyanide consumption. The high strength of the barren solution was caused by the necessity of adding lump cyanide at the head of the precipitation process to insure low-grade solutions to be used in washing.

"With the installation of our vacuum system, we found that perfect precipitation could be maintained without the addition of lump cyanide, and today our mills are running with the highest solution strength in the agitators, and not in the barren tank. This, together with a generally lower solution strength in all parts of the mill, has allowed a material reduction of cyanide consumption."

J. V. N. DORR, in commending the paper, said that in his opinion Mr. Crowe had made the greatest single improvement in the chemical end of cyaniding in the last 20 years, while Mr. G. M. TAYLOR, manager of the Victor and Independence Mills said that in these two plants the saving in zinc and cyanide, in treating 2000 tons of ore daily, amounted to \$30,000 per year. Chairman CLEVINGER said that without endeavoring to detract from Mr. Crowe's work in the least he thought the same thing had been done inadvertently in vacuum filtering in Butters' type machines for many years.

G. T. HANSEN said that in his practice he found that heating the pregnant solutions to 170 deg. F. to precipitate copper partially accomplishes deoxidation of the solutions, although at a higher cost.

**Roasting Cripple Creek Ores for Amalgamation and Cyaniding.**—A. L. BLUMFELD and J. M. TROTT described the methods used at the Golden Cycle custom mill. They bed as class A ores containing less than 2 per cent CaO, and higher lime ores, which require 50 per cent longer time in the roaster ore separately bedded as class B. The crushed ore is fed to an Edwards duplex roaster; operating details, temperatures, and mechanical features, together with the chemical reactions normally proceeding, are explained at length.

The production of soluble sulphides and sulphates must be avoided because of its action as a cyanide, and in deoxidizing the solutions. "Calcium sulphate, formed either in the roasters or by reaction of soluble sulphates in the ore on meeting the lime in solution, is decidedly

deleterious. The hot ore warms the crushing solution. This becomes saturated with calcium sulphate and precipitates as the solution cools. These crystals fill pipes, launders and Dorr thickeners, render filter mats and clarifying mats impermeable, coat Merrill filters, frames and cloths and form a deposit on the zinc and zinc boxes. In class A ores these troubles are comparatively unimportant, although considerable time is required to neutralize the solutions, whereas class B ores often require none."

While an "over-roast" will produce excellent results in a standard cyanide plant, a better residue can be obtained by a cheaper and less complete roast if the amount of soluble sulphide, total sulphur, HCl-soluble and  $\text{Na}_2\text{CO}_3$ -soluble sulphur is held under close control by chemical analysis.

"The limits of insoluble sulphur are: Class A, 0.10 per cent; class B, 0.15 per cent. The limits of soluble sulphide are: Class A, 0.10 per cent; class B, 0.15 per cent.

"Experience has shown that class B ores give good residues with higher total and insoluble sulphur and soluble sulphide, than class A. The chemical reasons for this are still obscure, but it is possible that the interaction between the sulphates and sulphides in the roasters, as noted above, gives a larger amount of each as a secondary reaction, and these then do not have so deleterious an effect in the treatment."

In order to adopt this delicate treatment certain details of the treatment subsequent to roasting were essential. Thus, blankets catch the coarse coated gold much better than do plates. The colloids must be eliminated so that the ore may be leached exceedingly fast. Otherwise a "slip-up" in one roaster will cause a rich residue by complete deoxidation of the solution. Removal of colloids is effected in a Dorr bowl classifier. A further precaution to be observed is that "change of solution must be made quickly to allow a good margin between an over-roast and an under-roast. On the sands, this is done by the back flow or wash solution in the classifiers."

Leaching tanks must be quickly filled with a semi-dewatered product in order that the sands may not rest too long in a dead solution in the early stages. Slimes must be aerated soon after classification, and more time must be given for agitation.

**Excavating Tailings at Ajo.**—Following as it did the film of the New Cornelia's operations, Mr. FRANKLIN MOELLER'S paper describing the Hewlett tailing excavator in operation at Ajo was enhanced in value. This excavator empties one of their 5000-ton leaching tanks each night. It is entirely similar in principal to the iron ore unloaders so familiar along the lower Great Lakes, with, of course, many minor modifications to fit the conditions at this plant. As Mr. E. P. MATHEWSON pointed out, the mechanical and electrical control stops which prevent the bucket from digging closer than six inches from the side walls and bottom of the tanks has resulted in an uninjured lead-lined tank which is the prime desideratum in any leaching operation.

**Grinding Resistance of Various Ores.**—A very important paper by LUTHER W. LENNOX, presented preliminary results of an investigation still under way.

"In an attempt to investigate the relative grinding resistances of a number of ores now being milled in this country and Alaska, the management of the Portland mills requested samples of average mill-run of ore from various companies. The request met with a ready response, indicating the desire of all operators to gain information on the subject." A quantity of each ore was coarse crushed and separated in various sizes, from which fractions a "standard feed" was prepared according to the following table:

| PREPARED STANDARD FEED |       |                        |
|------------------------|-------|------------------------|
| Mesb                   |       | Cum. Per Cent Retained |
| 10                     | ..... | 12 95                  |
| 14                     | ..... | 27 98                  |
| 20                     | ..... | 39 47                  |
| 28                     | ..... | 49 88                  |
| 35                     | ..... | 57 11                  |
| 48                     | ..... | 63 01                  |
| 65                     | ..... | 68 71                  |
| 100                    | ..... | 74 01                  |
| 150                    | ..... | 79 69                  |
| 200                    | ..... | 82 41                  |

One pound of this prepared ore, one pound of water, and 74  $\frac{3}{4}$ -in. steel balls were then placed in a small tube-mill, 8 x 12 $\frac{1}{2}$  in., rotated at 84 r.p.m. for a definite time, dried and screen-analysed.

"The method adopted for computing the results is that of Rittinger based on the law that work done in crushing is proportional to the surface exposed by the operation, or to the reciprocal of the diameter. For plotting the screen tests, the mesh (reciprocal of diameter) and the cumulative per cent of oversize are used as coördinates. The area between the feed and product curves will be proportional to the 'apparent work' done. The apparent work is in turn inversely proportional to the resistance of the ore to grinding; hence, the area between the curves is inversely proportional to grinding resistance.

"Unfortunately, we are unable to deal accurately with the material below 200 mesh, which is where most of the work done is represented. Microscopic measurements seem to offer the only accurate method. Curves plotted in the area below 200 mesh seem to follow no definite law, as that of a hyperbola. Many operators may feel but little interest in what happens after a certain fineness (say 48 mesh) is reached, but this does not render it necessary to measure the total work done on the whole of the ore."

The following table gives the comparative grinding resistance of various ores as determined by this method:

| Comparative Grinding Resistance | Source of the Ore                    |
|---------------------------------|--------------------------------------|
| 1.33                            | Calumet & Hecla jig tails.           |
| 1.16                            | British Columbia, Tonopah, Belmont.  |
| 1.00                            | Portland mill-feed (Development Co.) |
| 0.94                            | Smuggler Union.                      |
| 0.92                            | New Cornelia Copper Co.              |
| 0.83                            | Liberty Bell.                        |
| 0.81                            | Butte and Superior.                  |
| 0.80                            | Humboldt mine (Smuggler Union).      |
| 0.80                            | Tonopah, Belmont.                    |
| 0.79                            | Goldfield Con., ryanide feed.        |
| 0.71                            | Goldfield Con., flotation feed.      |
| 0.71                            | Alaska Treadwell, quartz & schist.   |
| 0.70                            | Miami Copper Co.                     |
| 0.69                            | Alaska Gold Mines Co.                |
| 0.63                            | Homestake, unaltered ore.            |
| 0.63                            | Arizona Copper Co.                   |
| 0.61                            | Nevada Con., pit ore.                |
| 0.53                            | Morenci, Phelps-Dodge.               |
| 0.53                            | Calumet & Arizona, roaster ore.      |
| 0.52                            | Alaska Treadwell, schist.            |
| 0.46                            | Copper Queen, mill feed.             |
| 0.38                            | Tuck Copper.                         |
| 0.37                            | Ray Consolidated.                    |

R. B. KILIANI in favorably commenting on the paper said that it would prove a god-send to those who had to "guess" at the proper grinding equipment to install

in a new mill. Given the method, the comparative grinding resistance could now readily be determined with very simple apparatus, following which definite information as to just what each type of ball-mill could be expected to do could be immediately had by referring to the performances of that grinder already operating in another mill having ore of approximately the same relative resistance.

### WEDNESDAY, SEPTEMBER 4

The party left Colorado Springs by special train for the Cripple Creek district where the day was spent at the mines and mills. In the early days of Cripple Creek the ore was mostly shipped to smelters but very soon mills were located at Colorado City and Florence. With the decreasing value of the ore, however, came the necessity of building local mills by the Independence, Portland and Vindicator companies. This has rendered possible the treatment of dumps, waste and low-grade ore reserves.

The cyanide process as now applied to the higher-grade Cripple Creek ores is briefly as follows: Coarse-crushing in rolls; roasting in Edwards, Pearce turret or Holthoff furnaces; passing the pulp over blankets for recovery of free gold; fine-grinding in tube or Chilian mills. The pulp is then treated either by straight agitation and filtration, or, after desliming, the sand is leached and the slime agitated, thickened to a suitable density, and filtered.

### Radium

The technical session held in the evening at Colorado Springs was opened by an interesting lecture on radium by Dr. RICHARD B. MOORE of the Bureau of Mines. He exhibited some of the radium products recovered by the joint efforts of the National Radium Institute and the Bureau of Mines. In the discussion Mr. W. A. SCHLESSINGER pointed out the fact that many carnotites contain soluble sulphates which precipitate dissolved radium; also that the available carnotite comes from many different localities, necessitating different treatment according to the nature of the ore. Low-grade carnotites can be concentrated, but the concentrate is so very fine and so hard to filter that it is almost impossible to extract the radium contained. Luminous paint has been largely developed within the last year, and is a mixture of the purest zinc sulphide and radium in suspension in a quick-drying varnish. About 500 milligrams per month is being consumed for this purpose alone.

### Molybdenite in Colorado

Mr. D. H. HALEY described the operations at Climax, Colorado, where low-grade deposits are being developed. Treating 0.9 per cent MoS<sub>2</sub> ore yields a recovery of 10 lb. of MoS<sub>2</sub> per ton. While the ore-dressing is still in a state of development, most of the losses are due to the presence of oxides. Promising laboratory methods for sulphidizing these have been discovered which reduce the tailings to 0.15 per cent MoS<sub>2</sub>, but the necessary reagents are not now available in quantity. At present they are increasing the capacity of the mill to 1000 tons per day, which will have an output far in excess of the whole previous world's supply.

### THURSDAY, SEPTEMBER 5

**Electrostatic Precipitation.**—On Thursday evening there was a most interesting discussion of this subject, deferred from Monday's program in Denver. Mr. DORSEY LYON was in the chair.

In the original paper of Mr. ESCHHOLZ he pointed out that the possibilities of electrostatic precipitation were known a century ago, but that its practical application awaited the perfection of the alternating-current transformer. Operating conditions require very rugged equipment because it must bear the brunt of occasional surges caused by treater breakdown, and the periodic oscillations produced at each half cycle on breaking the rectifier arc.

The problem of converting high-tension alternating current to high-tension unidirectional current has received considerable attention. Although many devices, such as mercury rectifiers, hot-cathode converters, or kenotrons, high-voltage direct-current generators, unsymmetrical electrodes, etc., have been advocated, the mechanical rectifier is still in use on practically all commercial treater circuits.

The mechanical rectifier makes a positive separation between the alternating current supplied to it and the unidirectional impulses sent to the treater, occurring when electrode separation draws the arc to the breaking point. The rectifier cannot, of course, suppress a sustained short-circuit caused by complete breakdown in the treater chambers, or by contact of electrodes. Under such conditions, it operates to limit the current until the circuit breakers open.

A delicate oscillograph shows that the voltage sustained across the treater is almost constant, its effective value reaching 97 per cent of the peak. This sustaining of the treater voltage is caused by the comparatively slow rate of treater discharge. In fact, under the usual condition of moderate clearance of gas at a velocity of 6 ft. per second, obtained in a tube 12 in. diameter, 15 ft. long, the average velocity of the dust particles, at right angles to the gas stream is, roughly but 0.8 in. per second, while complete precipitation of the same number of particles during the interval between breaking and making rectifier contact would require a velocity of 900 in. per second.

Systems depending upon the use of a mechanical rectifier for the conversion of high-tension alternating current to direct current may be classified with respect to the source of power.

A. Low-tension alternating-current generator for treater load only:

- (1) Single-phase generator supplying power to single transformer-rectifier-treater unit.
- (2) Single-phase generator supplying power to two or more transformer-rectifier-treater sets operated in parallel on the low-tension side.
- (3) Multi-phase generator supplying energy to one or more transformer-rectifier-treater sets from each phase.

B. Low-tension alternating-current industrial or lighting mains having a relatively large capacity as compared with treater demand, and supplying one or more transformer-rectifier-treater sets.

C. High-tension alternating-current main supplying energy directly to potential regulator-rectifier-treater sets.

The author strongly prefers system A-1. Other systems than those mentioned have been urged from time to time on the score of low cost, but the author points out that the advantage of low first cost is illusory since the electrical equipment costs only from 10 to 15 per cent of the cost of the treater and is only 2 to 7 per cent of the value of the yearly recovery.

In discussing the electrical features of the process Mr. FISCHER of the Research Corporation said that system A-1 is widely and correctly used in large sectionalized plants, but that system B is simplest and will become more popular. It must be installed in large-capacity circuits. Resistances are valuable because they absorb the surges. System C has never been seriously applied.

Mr. VIETS of the Research Corporation said that the transformer in system A may reflect surges like a mirror back to its closely connected generator. System B produces fewer oscillations building up dangerous electromotive forces. The treaters at Tooele were changed from system A-1 to B because the latter gives precipitation due to the increased power input which is possible, and a smoother wave form is produced. No undesirable surges are produced in the main smelter circuits. On the other hand Mr. MURPHY of Anaconda said that in the huge new plant being built, system A-1 will be used. Extensive tests were made on A-1, A-2 and B, using a seventy-five kilowatt experimental unit. System A-2 was discarded because of anticipated operating troubles. Costs of A-1 and B are practically identical. Testing showed that precipitation to be best, with most perfect wave form, which can be had with a specially designed motor-generator set and independent of fluctuations in supply-current wave form. Mr. E. P. MATHEWSON said that the following practical points should be discussed: How much humidity is necessary for good precipitation. He cited the experience of one plant where forty per cent is considered best while at Miami the treater on the ore dryers makes an excellent recovery. He also wished information regarding the effect of the nature of solids on the efficiency, saying that zinc oxide is notoriously hard to precipitate. Mr. SOCKETT of Tooele said that converter fume was treated best when sprayed, but that the formation of sulphuric acid was to be avoided. Fume is hardest to precipitate but dust is easy. Mr. RICKETTS said that Miami gets a white precipitate from its converters, recovering all the copper but passing all the zinc oxide. Mr. VIETS said that the Research Corporation's work showed that most careful humidification was necessary on zinc oxide. Mr. SOCKETT of Tooele said that the annual repair cost on the Dwight and Lloyd precipitator is 20 per cent. The net yearly recovery of fume is 38 per cent on the Dwight and Lloyd and 56 per cent on the converter precipitator.

Platinum was first discovered in South America in a section of what is now the Republic of Colombia. Although users of this metal must now depend for their supply practically entirely upon the Colombian mines, since Russian sources of supply have been temporarily abandoned, there appears to be no danger of these resources being exhausted.

## French Chemical Industry and the War

"If it were necessary to decide," said a French writer in the *Revue des Deux Mondes* of July 18, "which of all things produced by industry has been most needed and useful to the country since the war began, and without which defeat would have been rapid and inevitable, I should reply without hesitation that it is sulphuric acid."

It has long been an economic maxim, he continued, that the factor which best represents a nation's economic progress is its consumption of sulphuric acid. It is the very life blood of war industries. In the two years preceding 1914, Germany overstocked herself with 600,000 tons of pyrites to make sulphuric acid beyond her normal requirements. These figures may be drawn from her imports from Spain and they furnish an eloquent though silent answer to the attempted German excuses for that nation's great crime. Inasmuch as the war has lasted longer than was the design of the authorities at Berlin they have had recourse to Norwegian pyrites and have cut down the allotment, for the German fertilizer industry normally requires for superphosphates alone some 600,000 tons of this leading chemical product. Bitter complaint has arisen from the farmers because of this restriction in the production of fertilizers.

The reason why sulphuric acid is needed is, among other things, to make gun-cotton or nitrated wood pulp, for smokeless powder. The cotton or pulp is first treated with nitric and sulphuric acids, after which it is dissolved into a gelatine-like mass to make it insensible to shock and then it is cut into the prismatic disks which constitute smokeless powder. The proportions of nitric to sulphuric acid required to make gun-cotton are respectively one to three, although no part of the sulphuric acid is present in the final product. The purpose of the sulphuric acid is to combine with the water which is produced by the action of strong nitric acid upon the cotton or cellulose, because as soon as more than a very slight amount of water is present the reaction stops. Something must be added to take up all the water that is formed and an excess of concentrated sulphuric acid will do it, because it is one of the thirstiest bodies known to chemists. But the more it gets the less it wants, so that only a very strong acid will serve the purpose. Ordinary chamber acid such as used in the fertilizer industry will not do at all. What is really needed is oleum or fuming sulphuric acid, and to make this economically the only thing in the world that will answer is platinum.

When the war broke out the monthly production of sulphuric acid in France was only about 5,400 tons per month, mostly at the St. Gobain works, while the German production in times of peace the writer states to be 145,833 tons per month. The present French production, however, for war purposes alone has been increased to over 100,000 tons a month, somewhat approaching the present German production.

Members of the American Chemical Society have been very much interested in this substantial advance in the French manufacture in view of the daily increasing needs for sulphuric acid as the Allied army grows in numbers as well as power.

# Starting and Stability Phenomena of Ammonia-Oxidation and Similar Reactions

"Conversion Curve" and "Heat of Reaction Line"—Influence of Temperature, Catalytic Poisons, Thickness and Number of Catalytic Gauzes—Velocity and Concentration of Reacting Gases

By F. G. LILJENROTH

IF THE temperature of the gauze or catalyst of an ammonia-oxidation burner is varied, but all other conditions such as mass flow, gas composition, etc., are maintained constant, the percentage conversion or the degree of reaction will in principle vary according to the curve shown in Fig. 1. At low temperatures there will be practically no nitric oxide formed, but at a certain temperature the conversion will begin to increase very rapidly because the reaction velocity is highly dependent upon the temperature. At still higher temperatures the ammonia will begin to decompose into its elements, and the rate at which the conversion increases will be lower; or in other words, the shape of "conversion curve" will change from convex to concave and at a certain temperature, which I understand is somewhere around 750 deg. C., the conversion will reach a maximum of nearly 100 per cent. Thereafter, the conversion will again decrease and reach a zero value at a fairly high temperature.

The heat of reaction within the temperature limits in question is practically constant and equals about 53,000 gram-calories for each gram-molecule of nitric oxide formed. If we assume a 100 per cent conversion and the presence of, for instance, 9 molecules of air for each molecule of ammonia in the initial gas mixture, then the temperature rise of the gas current due to

the heat of reaction will be equal to  $\frac{0.95 \cdot 53,000}{7.4 (9 - 1)}$  or 675 deg. C., assuming 5 per cent heat-losses by radiation or convection. If the temperature of the ingoing gas is 25 deg. C., then the temperature at the gauze will be 700 deg. C. The figure 7.4 represents the average molecular heat-capacity of the gas mixture at constant pressure. As the gas mixture consists principally of diatomic gases and as the temperature range is comparatively small, it is readily seen that this quantity is practically independent both of the conversion percentage and of the temperature, and that it can with great accuracy be put equal to 7.4.

If the ammonia content in the initial gas mixture is maintained constant, the temperature rise due to the heat of reaction will increase in proportion to the conversion and the temperature of the gauze is graphically represented by the straight line in Fig. 1. This line refers to an initial gas composition of 9 to 1 and to a temperature of the ingoing gas of 25 deg. C. To any other gas composition and to any other temperature of the ingoing gas there corresponds another line. I wish to call particular attention to the fact that in order not to complicate the problem, I have deliberately disregarded the heat of reaction due to the dissociation of ammonia into its elements and other secondary reac-

tions which take place principally at the descending part of the conversion curve. Such a first approximation is permissible because the losses are in any case small.

## GENERAL CONDITIONS OF STABILITY

The straight line, which will be called the "heat of reaction line," cuts the "conversion curve" ordinarily at two points, *a* and *b*, Fig. 1. It seems, therefore, as if it would be possible to have two points of operation for any burner at a given gas composition and gas flow. But a closer investigation shows that the reaction cannot be maintained at the point *b* because the conditions for stability at this point are not fulfilled. Suppose that the burner is working at this point and that for some reason the temperature decreases by the small amount of *dt*. Then the conversion will decrease to point 1. This decrease will cause the temperature to be lowered still more, to point 2, and this will in turn

FIG. 1.—CONVERSION CURVE. VELOCITY AND CONCENTRATION OF GAS CONSTANT

cause a new decrease in the conversion, to point 3, and so on. In other words, the burner will go out.

If we assume that for some reason the temperature increases, it will in the same way be found that even in this case we will move away from the point of intersection, which is indicated in the figure by the arrows pointing apart from this point.

If we treat the other point of intersection similarly (point *a*), it will be found that conditions are just opposite. If for some reason we depart from the point, we will immediately be carried back to it, which fact is

indicated by two arrows both pointing toward the point. Point *b* is therefore an unstable location while point *a* is a stable one. As can easily be understood, this characteristic difference depends upon the manner in which the heat of reaction line cuts the conversion curve. In

FIG. 2.—CONVERSION AT IGNITION POINT

order to obtain stability the heat of reaction line must cut the conversion curve from below, and from this it follows that the part of the conversion curve to the left of the tangential point *c* is unstable, but that the part to the right is stable. It will also be understood that the stability or instability increases with increase in the size of the angle at which the line and the curve cut each other.

#### STARTING OF THE REACTION

From what has been said regarding the instability of the point *b*, we can now understand that the ammonia-oxidation process is not self-starting or self-exciting, but that the gas, in order that the reaction may be started, must be heated by a flame or by electricity to at least such a temperature *T* that the resulting line becomes a tangent to the ascending part of the conversion curve, as is shown in Fig. 2. In such a case the reaction will start and after a short time arrive at point *e*. After this the starting flame can be removed and the reaction will move to point *a*. This not only makes it very clear whether and why the ammonia oxidation or any other continuously operated catalytic reaction is self-starting or not, but it also gives us a method by which to predetermine the temperature *T* which is necessary to start the reaction. This "ignition-temperature," as seen from Fig. 2, is always much lower than the reaction-temperature; or, in other words, it is not necessary to heat the reaction to its full temperature but only to help it overcome the obstacle formed by the ascending part of the curve. When this obstacle has been overcome, the reaction will take care of the rest itself and work up to the full temperature.

The temperature necessary to start the reaction can be decreased by using a gas mixture richer in ammonia, because the position of the heat of reaction line will be lowered. This is indicated by the lines *fk* and *tm* in Fig. 2. I understand that this method of starting is really used in some oxidation plants.

The shape of the conversion curve of all continuously operated exothermic catalytic reactions is in principle the same as that of the ammonia oxidation. It ascends at first, due to the fact that the reaction velocity increases with the temperature, but as it is limited by the always descending equilibrium curve, it must sooner or later reach a maximum; thereafter it begins to descend. (In the ammonia-oxidation process the descent begins earlier than would be expected from the equilibrium curve, this being due to the fact that another reaction, the decomposition of ammonia into its elements, begins to take place at higher temperatures beside the oxidation reaction.) The possibility that there are continuous exothermic reactions which are self-starting is therefore not excluded, because the only condition that needs to be fulfilled is the necessity of having the conversion curve from the beginning lie above the heat of reaction line.

An example of a self-starting reaction is offered by the long known fact that the hydrogen-air or hydrogen-oxygen flame can be ignited by means of a small piece of platinum sponge. This is represented in principle in Fig. 3. The lower curve corresponds to the non-catalytic reaction which, as may be noted, is not self-starting. By using a strong catalyst the curve is raised so that from room temperature and up it lies above the heat of reaction line, this being the general condition for self-excitation. The temperature of the platinum sponge will consequently increase to the point *a* which is always above the ignition temperature *T* of the non-catalytic reaction. The fact that a hydrogen flame can be ignited by means of spongy platinum induced inventors to try the same experiment with ordinary coal gas. It was found, however, that the platinum sponge began to glow but that the gas would not ignite. This

FIG. 3.—CONVERSION. SPONTANEOUS IGNITION

was explained by saying that coal gas is not so inflammable as hydrogen and that the temperature of the platinum sponge was too low.

How can this fact now be brought into agreement with our theory? The explanation is very simple. The

<sup>1</sup>As can easily be shown by Nernst's "New Theorem" that the ammonia-nitric oxide equilibrium is, within the temperature limits in question, practically constant and above 99.99 per cent. For obvious reasons this equilibrium cannot be determined experimentally.

radiation of the ignition system is very large, even if the radiation of the whole system is zero, and to the ignition-conversion curve (the upper curve) belongs, therefore, not the same heat of reaction line as to the main conversion curve, but a line much further to the left. If the point of intersection *b* between this line and the catalytic conversion curve corresponds to a lower temperature than *T*, it can be seen that the platinum sponge will begin to develop heat without being able to ignite the gas. In order to raise the temperature to *T* we can place two pieces of platinum sponge in series so that the gas arrives at the second one, preheated to such a temperature that the final temperature is higher than *T*. If it is not enough with two, we can put three pieces in series.

Numerous other arrangements have been proposed in order to ignite the coal gas flame by means of platinum sponge, and the reasons why one arrangement works better than another, or why it does not work at all, are very vaguely stated in the literature, but with this explanation become extremely clear and simple.

#### DETERMINATION OF THE CONVERSION CURVE

The heat of reaction line can be very easily determined both theoretically and experimentally, but the conversion curve can be determined only by experiments. Points on the descending part to the right of point *a* (see Fig. 2) can be determined by preheating the ingoing gas to different temperatures; at the same time we can also obtain the part of the curve which is left of point *d*. The part of the curve between *a* and *c* can be determined by increasing the heat losses, for instance by water cooling the burner. The unstable part of the curve between points *c* and *d* cannot be determined directly, but it can be determined indirectly by extending the stable parts of the curve and connecting points *c* and *d* in an intelligent way. In case the temperature, caused by the heat of reaction, is small, which for instance is the case in the Haber process (due to both the low heat of reaction and the low conversion obtained), the unstable part of the conversion curve will be very short. Practically the whole conversion curve can be determined therefore simply by cutting out the heat exchanger and heating the gas electrically, keeping a constant current or voltage.

#### PRACTICAL CONDITIONS OF STABILITY

It has been noted that the only condition which needs to be fulfilled in order to keep a reaction going, when it once has been started, is the necessity of having the heat of reaction line cut the conversion curve from below. We would expect therefore that it should be possible to work at the maximum point of the conversion curve because this point is on the right side of point *c* where the stability zone begins (Fig. 2). This also is possible under ideal conditions, that is, if gas composition, gas flow etc. are maintained absolutely constant. In practice, however, there will always be small variations in gas composition and gas velocity which cause the heat of reaction line and the conversion curve to change their positions continuously. If, for instance, the ammonia content in the ingoing gas for some reason decreases, the heat of reaction line will turn counterclockwise around its point *f* on the abscissa. If it turns past the tangential position *c* and remains there long

enough for the gauze to cool below the ignition temperature, the burner will go out. This time, which by the way can be calculated exactly if the conversion curve is known, is very short because the gauze is rapidly cooled by the incoming cold gas mixture, the heat capacity of the gauze and the walls being comparatively small.

The conversion curve is also affected by the gas composition and besides that by the gas velocity. As already noted, both of these quantities vary in practice a few per cent and consequently the heat of reaction line and the conversion curve will both oscillate around an average position. Ample margin between points *a* and *c* must therefore be provided. If the top of the conversion curve is sharp, it will be impossible to work at a maximum efficiency, because we have to move the working point further to the right side, sacrificing efficiency in order to obtain stability. This also implies higher temperature. If the conversion curve is very flat, which seems to be the case in the ammonia-oxidation reaction, it will be possible to work not only at the top point but even a little to the left of it. As far as I understand, this is really what is done in the ammonia-oxidation process if no heat exchanger nor any additional heat above the heat of reaction is used. A decrease in the radiation losses will consequently improve not only the stability but also the efficiency. If the radiation is decreased as much as possible, and if we are still on the ascending part of the conversion curve, the only way to reach the top is to use a heat exchanger or some additional heat. If we are very near the top it will probably not pay to go into this complication.

The margin of stability must be greater, the greater the variations in initial gas strength and gas velocity. It is therefore of importance to keep the motors at a constant speed driving the ammonia and air-blowers and in general to keep the gas current as steady as possible. Of how great importance this is can be determined only if conversion curves of a number of different gas compositions and different gas velocities are known.

#### INFLUENCE OF CATALYTIC POISONS UPON STABILITY

If occasionally the steadily flowing gas current should carry along some foreign gas, we would have the same kind of disturbance as we would if the ammonia content varied. If the foreign gas or matter is not indifferent, or if it acts as a poison to the catalyst, the disturbances may be still worse. In such cases still more margin must be provided; that is, we must work further to the right of the maximum point (see Fig. 4) which means a higher temperature and a decrease in the conversion from point *a* to, for instance, point *g*. We must now remember that the conversion curves always refer to absolutely pure gas mixtures and we will have therefore in addition to this decrease another reduction depending upon the frequency, the nature, and the duration of the impurities.

This can be stated also in another way. In a plant where such impurities are likely to appear, we must safeguard ourselves against the burner going out by working with more ample margin; that is, even if for some length of time the gas happens to be pure, we will still have a lower efficiency than in a plant where we

know the gas mixture to be constantly pure. When the impurities appear, however, we will have an additional loss, but the loss cannot, of course, be precalculated but only estimated from practical experience.

The first kind of loss can be measured exactly by running the burner with pure ammonia at the same gas flow and gas strength as when the impure ammonia is used. It can also be determined from the conversion

FIG. 4.—CONVERSION. CATALYTIC POISONS

curve in the following way: Suppose the gauze is heated by electrical energy but that no heat exchanger is used, and furthermore that the electrical power consumed is equal to 0.03 kw.-yr. per ton of  $\text{HNO}_3$  which equals  $\frac{0.03 \times 8760 \times 3600}{4.2}$  kg. cal. per ton of  $\text{HNO}_3$ ,

which in turn equals  $\frac{0.03 \times 8760 \times 3600}{4.2} \times \frac{63}{1000}$  or 14,000 kg. cal. per kg. mol. of  $\text{NH}_3$ .

The temperature rise due to the electrical heating alone will hence be  $\frac{14,000}{7.4(9+1)}$  or 190 deg. C. If this temperature is added to the plain heat of reaction line, we get a line (*hg*, Fig. 4) beginning at  $190 + 25$  deg. C., and ending at  $700 + 190$  deg. C. This line cuts the conversion curve at point *g* and we can thus find the conversion and the loss. The temperature rise of 190 deg. C., due to the electrical heating, could also have been determined experimentally by running the burner with a normal gas flow and a normal electrical energy but without igniting the burner. This test can be run just as well with ordinary air as with ammonia-air mixture, thereby saving the ammonia.

In the ammonia-oxidation process it happens that if the radiation losses are small, the reaction itself develops just about enough heat to give the proper temperature, or in other words, the heat of reaction line cuts the best conversion curve in the neighborhood of the top just far enough to the right of the point *c* to secure stability, assuming that pure raw materials (for instance, high-grade coke-oven aqua ammonia) are used. In case the ammonia contains impurities, poisonous to the catalyst, as seems to be the case with cyanamide-ammonia, higher temperatures must be employed in order to secure stability, as has been shown above. This can be done either by using a heat exchanger, line *fg* (Fig. 4), or by supplying some additional heat, line *hg* (Fig.

4). As there is always a time lag in the action of any heat exchanger the temperature will not decrease instantaneously as the impurities come along. If, therefore, the impurities are of short duration with fairly long intervals, the use of a heat exchanger may be preferable to the plain heat of reaction method, assuming that it could be employed here. If, on the other hand, the impurity periods are long and the intervals short, it will be understood that the heat exchanger is inferior to the plain heat of reaction method.

This is a true analogy to the action of a flywheel in connection, for instance, with a rolling mill. In a blooming mill very heavy flywheels are used, whereas in a wire mill the rotating masses must be made as small as possible. The employment of additional heat, either by preheating the gases in a fuel-heated furnace or by electrically heating the gauze, gives the most stable conditions, especially if the external heat alone gives a temperature which is higher than the ignition temperature, in which case the burner ignites itself again as soon as the impurities have passed, supposing that these were of such magnitude so as to cause the burner to go out. It is not very probable that this is the case in any ammonia burner because it would mean unnecessarily high stability, very high temperature and very low efficiency. On the contrary, even electrically or fuel-heated burners must be ignited by a flame or coil or by increasing the current in the gauze above the normal value.

In regard to fuel heating versus direct electrical heating of the gauze, we would expect one method to be just as good as the other, assuming that the electric current has no direct activating influence on the platinum.

Such an influence is very improbable in view of the excellent results obtained without the use of electric heating; this has probably been adhered to as an easy way of explaining the fact that the direct electric heating gives higher stability than if the same amount of additional heat is supplied outside the gauze. The following explanation seems to me much more plausible. The electrical resistance of platinum as well as of other metals increases with the temperature. At 700 deg. C. it is about 3 to 4 times as high as at 0 deg. If, therefore, due to a weakening of the gas strength or to poisonous impurities, the gauze begins to cool and blacken, the current flowing through it will immediately increase in the same proportion as the resistance decreases. Furthermore, as the heat developed is proportional to the square of the current times the resistance ( $I^2R$ ), it follows that the electric energy converted into heat will increase when the temperature decreases. This phenomenon is the more marked, the less external electric resistance there is connected in series with the gauze. If the external resistance is equal to or higher than the internal, the reverse condition will prevail and it may be necessary to use a costly automatic constant current regulator. If none or only a very small amount of external resistance is used, it is not only useless but detrimental to use automatic regulation. Further investigation of this problem leads to very interesting conclusions in regard to the manufacture of the gauze and the arrangement of the electrical heating and starting. Besides this "electrical influence," the electric heating has the advantage of having the heat supplied directly within the metal,

whereas with outside heating the heat must first travel from the gas to the metal.

It has been noted that when using even pure raw materials ample margin of stability must be provided to take care of the oscillations in the heat of reaction line and in the conversion curve, because of variations in the gas strength and gas velocity. We will discuss this matter more in detail.

INFLUENCE OF GAS VELOCITY

The gas velocity has no influence upon the heat of reaction line but affects the conversion curve in the following manner: At low temperatures, where practically no ammonia dissociation takes place, the conversion is higher the lower the gas velocity, because the time of reaction is longer and the reaction consequently comes closer to equilibrium. At higher temperatures this increase is probably more than counterbalanced by the increase in ammonia dissociation due to the same conditions as the increase in the ammonia oxidation. If, therefore, the velocity corresponding to our working curve is called 100 per cent, the curves corresponding to 90 per cent and 110 per cent will probably have the positions and shapes indicated in Fig. 5.

It can be easily seen why the stability decreases when the gas velocity increases and why the flame can be "blown out." If the velocity decreases, the stability will at first increase, but probably decrease later on. If this were not the case, it would be possible to get the reaction to start without the use of an ignition flame simply by increasing the gas velocity very slowly from zero up.

As seen, I have shown the 110 per cent curve having a higher peak than the 100 per cent curve. If this really is the case, there is a double reason why we should increase the working velocity and at the same time increase the temperature by, for instance, introducing a

FIG. 5.—VARIATION OF CONVERSION WITH VELOCITY

heat exchanger. The output of the plant will increase not only in proportion to the gas velocity but also in proportion to the conversion. If we increase only the gas velocity without changing the heat of reaction line the conversion will go down, probably more rapidly than the velocity will go up, resulting in a lower output instead of a higher one. Besides this the stability will rapidly decrease, as already noted.

INFLUENCE OF GAS STRENGTH

The influence of the variations in the ammonia content of the gas mixture upon the stability is more complicated because such variations influence both the heat of reaction line and the conversion curve. This first influence is very simple; the heat of reaction temperature at a certain conversion increases in proportion to

FIG. 6.—VARIATION OF CONVERSION WITH CONCENTRATION

the ammonia content (see Fig. 6). The latter influence, however, is very complicated and the only guess I would like to make is that at lower temperatures the conversion increases with the gas strength. If the curves for different gas strengths appear as is indicated in Fig. 6, we can understand that the stability will be greatly increased if the gas strength increases, because the heat of reaction line moves to the right and the conversion curve to the left. Conversely, the stability will rapidly decrease when the gas strength is weakened.

What has been said regarding the possibility of improving the process by decreasing the time of reaction and by introducing at the same time a heat exchanger can also be applied here if we substitute gas strength for time of reaction and assume that the conversion curve in principle moves as indicated in Fig. 6.

If the curve, on the contrary, moves to the right instead of to the left when the gas strength increases, the stability will be practically unaffected by changes in the gas strength, because the heat of reaction line will oscillate synchronously with the conversion curve.

OXYGEN INSTEAD OF AIR

If the ammonia gas is mixed with oxygen instead of with air we must for economical reasons work with a very high ammonia content in the ingoing gas. The heat of reaction line will consequently turn clockwise a very big angle, giving a temperature several times higher than that when using air at the same conversion. If the conversion curve has the shape assumed and if this shape is not materially changed by the exclusion of the nitrogen, the result will be a higher temperature and stability, but a lower efficiency than if air were used. This can, of course, be corrected by water-cooling the gauze, but as when using air, the stability

is sufficient and the efficiency above 95 per cent, the use of oxygen is not justified, at least not for the sake of a possible increase of efficiency.

#### THICKNESS AND NUMBER OF GAUZE

In view of what has been said, the influence of the thickness and number of gauzes becomes very simple and clear.

The thickness of the gauze affects the conditions only in the matter of reaction time, assuming that the effective contact surface is changing in the same proportion as the contact time. A change of the thickness of the gauze, therefore, acts in the same way as a change in the gas flow. The result will be the same whether we double the gas flow, or decrease the thickness of the gauze to one-half. If the gas flow and the thickness of the gauze are both increased or both decreased in the same proportion, the conditions will not be changed at all.

The influence of the number of gauzes is the same as the influence of the thickness of the gauze, but only if the gauzes are placed very near each other and in good metallic connection so that the temperature is always the same in all the gauzes.

The problem is quite different and much more complicated if the thermal interconnection of the gauzes is incomplete. In order not to make the problem too complicated, I will assume the extreme condition that the gauzes are completely independent of each other thermally. This means that no other heat exchange can take place between the gauzes than by the way of the gas current. Let us assume that we have a burner working with, for instance, two gauzes, placed in complete contact with each other. If, now, the two gauzes are moved apart and thermally isolated from each other so that no heat can be radiated or conducted between them, the first gauze will act as if the velocity had been increased to double its value. If, before moving the gauzes apart, we were working in the neighborhood of the top of the conversion curve, the burner would probably go out, or at least work with less margin of stability. If the latter is the case, the temperature will change somewhat, but the efficiency will still be in the neighborhood of its maximum value, leaving practically nothing for the second gauze to do. If the burner goes out we have to use a heat exchanger or apply electric heating, or we have to decrease the gas flow in order to re-establish the stability. If we apply any of these means just sufficiently to get the same stability and efficiency as before, there will again be practically no work left to the second gauze. But even if we use these means in excess, or in other words, when we work far down on the descending part of the conversion curve, the second gauze will have very little to do because the losses in the first gauze are principally caused by ammonia decomposition. Only in case we work far down on the ascending part of the conversion curve would there be some ammonia left for the second gauze, but as previously shown, the ascending part of the conversion curve is practically all within the unstable zone. If this could in some way be made stable, the gas leaving the first gauze would have to be water-cooled before it entered the second gauze in order to prevent the latter from reaching too high a temperature and too low a yield.

In case platinum should become very scarce, such an arrangement might be advantageously used, in that a cheap low-grade catalyst could be substituted for the first gauze and the succeeding platinum gauze made to do the final work analogous to the method frequently used in the catalytic-sulphuric-acid process. But the first stage of the conversion must be worked in such a way that the greater losses will consist principally of

FIG. 7.—VARIATION OF CONVERSION WITH LOW GAS VELOCITIES

ammonia going unchanged through the catalyst; that is, we must work in the unstable zone, which might not be absolutely impossible.

#### SYNTHETIC-AMMONIA PROCESS

Here the conditions are still simpler because no disturbing reactions take place. The conversion curve has the same shape as in the ammonia-oxidation process. It first rises rapidly, reaches a maximum, and then begins to decrease because the conversion is limited by the falling equilibrium curve. If the gas velocity is decreased, the entire curve moves upward, and vice versa if the velocity is increased (see Fig. 7).

If seems, therefore, as if we ought to work with a very low gas velocity. This would be true if the conversion were the deciding factor, but because of the fact that the gas mixture is recirculated, the conversion is of only secondary importance. The deciding factor is the output, which is the product of gas velocity and conversion. The working point is therefore the top of the conversion curve at which this product is at a maximum. If, however, proper consideration is given to the cost of the ammonia removal and to the cost of the electric power, a new curve somewhat above this curve is obtained. Anyhow, we will assume that the curve marked velocity = 100 per cent is the most economical curve.

The heat of reaction is equal to about 14,500 g. cal. per g. mol. of ammonia at the temperatures in question. For each per cent of conversion, the corresponding temperature rise is thus equal to  $\frac{14,500}{7.25 \times 2 \times 100}$  or about 10 deg. C.

The corresponding heat of reaction line never cuts the conversion curve, which means that in the synthetic-

ammonia process, contrary to what is the case in the ammonia-oxidation process, a heat exchanger must always be used. Besides the heat exchanger, there must usually be supplied some additional (frequently electric) heat. The reason for this is that the heat of reaction is as a rule insufficient to cover the radiation loss and to create the temperature difference which is needed to keep the size of the heat exchanger within reasonable limits. If a high pressure and a good catalyst are used, the conversion will be higher, the heat of reaction will be sufficient, and no electric or other heat needs to be supplied from without except during the starting period, as can be seen from Fig. 7. The amount of electric power necessary for starting can easily be calculated if the conversion curve and the gas velocity are known. This power can be decreased if the gas velocity is lowered during the starting period, as seen from Fig. 7. It can also be noted that if the gas velocity is increased, the stability will decrease and vice versa. Ample margin of stability, therefore, must be provided; if the gas velocity is increased too much, the flame can be "blown out."

If no electric heat is used, the influence of the gas velocity on the heat of reaction line ought to be very small, because at the high mass flow per square foot here prevalent, the heat transfer (B.t.u. per sq.ft. per hour) of the heat exchanger walls is practically proportional to the gas velocity. The heat transfer is equal to the sum of two quantities, one of which is constant and the other proportional to the mass flow per square foot. If the mass flow per square foot is very large, as is the case here due to the high compression (100 to 200 atm. pressure) the constant quantity is negligible. If, after all, there is an influence depending upon a faulty design of the heat exchanger, this influence works to turn the heat of reaction line counter-clockwise when the velocity increases. As shown above, the conversion curve moves in the opposite direction. In such a case a still greater margin must be provided.

If electric heating is used but no heat exchanger, the resulting line is parallel to the heat of reaction line proper, and if a heat exchanger<sup>2</sup> but no electric heating is used the resulting line goes through the origin. Consequently, if both electric heating and a heat converter are used simultaneously, the resulting line is the sum of these two factors. If the gas velocity increases, the constant part of the temperature corresponding to the electric power decreases inversely as the gas velocity. Strange as it may sound, the reaction is therefore more sensitive for increases in gas velocity with electric heating than with only a heat exchanger.

The gas composition has no influence at all upon the heat of reaction line and practically no influence upon the conversion curve, which can be understood from the following. The conversion corresponding to equilibrium is approximately proportional to  $\sqrt{N \cdot H}$ , where H is the volume of hydrogen and N the volume of nitrogen present in a certain amount, say four volumes, of the mixture. If we are far from the point of equilibrium, the decomposition velocity is negligible and the conversion is consequently in proportion to  $H \cdot N$ . The follow-

ing tabulation shows that both  $H^2 \times N$  and  $\sqrt{H^2 \times N}$  are practically constants within wide limits:

| H   | N   | $H^2 \times N$ | $\sqrt{H^2 \times N}$ |
|-----|-----|----------------|-----------------------|
| 3.2 | 0.8 | 26.3           | 5.14                  |
| 3.1 | 0.9 | 26.8           | 5.17                  |
| 3.0 | 1.0 | 27.0           | 5.2                   |
| 2.9 | 1.1 | 26.8           | 5.17                  |
| 2.8 | 1.2 | 26.3           | 5.14                  |

The gas composition, therefore, has practically no influence upon the stability.

### CONCLUSION

In the same manner, many interesting conclusions can be drawn in regard to the starting and stability of other continuously working catalytic and exothermic reactions as, for instance, the sulphuric-acid process, the conversion of  $\text{CO} + \text{H}_2\text{O}$  to  $\text{CO}_2 + \text{H}_2$ , the conversion of  $\text{NO}$  to  $\text{NO}_2$  etc.

The method can probably be advantageously applied also to non-catalytic, exothermic, continuous or discontinuous (explosive) reactions, although the conditions here are much more complicated because the time of reaction in the first case is not an arbitrary constant but a function of the temperature, the gas velocity, the radiation etc. In the second case, the time of reaction is in itself an independent variable in addition to the independent variable which we already have, namely, the temperature.

It would be beyond the scope of this article to go into these questions, but I hope that the above examples have been sufficient to demonstrate the usefulness of the method of investigation set forth. It not only explains in a very simple manner the starting and stability phenomena and the influence of catalytic poisons on the stability, but it might also be useful for the further studying and improving of ammonia oxidation and similar processes. It is therefore desirable that pure raw material conversion curves be determined for different gas strengths and gas velocities, both for ammonia-air and ammonia-oxygen mixtures. If such curves were available, it would be possible to adjust or design a burner for a maximum commercial efficiency, giving proper consideration to conversion efficiency, output etc. This applies also to other processes.

Finally, I wish to point out that this article refers only to the method of investigation and not to any specific data. The shape of the curves and the figures given should be considered only as examples.

Washington, D. C.

### Treatment of Caustic Soda Burns

As the workmen in the kettle room of the caustic soda works are exposed to painful burns at the syphon line faucet while filling the drums as well as in handling the containers of the molten caustic, some emergency aid should be immediately available for treatments. Mr. M. Firsinger read a paper before the National Safety Convention at New York, in which he recommended a two per cent solution of acetic acid as an acid wash, followed by an oil dressing. Absorbent cotton should not be placed in immediate contact with the wound, but can be used on top of a lint-free pad saturated with vaseline, carron oil or other air excluder. Perhaps aluminium acetate would be a preferable form of neutralizer—especially in cases involving the eyes and lips. Aluminium soap would also be preferable to the lime water emulsions.

<sup>2</sup>A closer investigation shows that the most economical heat exchanger has such a high mass flow that the constant term is negligible.

# Slag Control in the Iron Blast-Furnace by Means of Slag Viscosity Tables

Application to Blast Furnace Operation of Viscosity Data Obtained in Former Investigation by Bureau of Mines—Method of Using Slag Viscosity Tables—Examples Demonstrating Their Application

BY ALEX L. FEILD

Research Physical Chemist, National Carbon Co., Inc., Cleveland, Ohio.

THERE has not been available until recently experimental data which were of any great assistance to the blast-furnace operator in his control of slag composition. The Bureau of Mines has completed an extensive investigation of the properties of slags at high temperatures over a wide range of compositions. The results of this work have been published as Bureau of Mines *Technical Papers* 157, 187, and 189, and also in several technical journals.<sup>1</sup>

By means of the viscosity data obtained in the investigation it is possible to decide upon the proper slag composition by a procedure which has as its basis a series of experimental measurements conducted with care and with due regard to the needs of the case.

*Technical Paper* 187, "Slag Viscosity Tables for Blast-Furnace Work," contains the complete slag tables and is written particularly for iron metallurgists. *Technical Paper* 157, "A Method for Measuring the Viscosity of Blast-Furnace Slag at High Temperatures," was the first preliminary report and contains a description of the apparatus and methods of measurement, together with viscosity measurements on a limited number of slags.<sup>2</sup> *Technical Paper* 189, "Temperature-Viscosity Relations in the Ternary System  $\text{CaO-Al}_2\text{O}_3\text{-SiO}_2$ ," contains the more scientific results of the investigation and in addition a description of the improvements made in experimental technique since the appearance of the preliminary paper.

## PURPOSE OF THE PRESENT PAPER

In former publications, purporting to be nothing more than a permanent record of experimental measurements, it was advisable to give only a few brief suggestions as to the actual application of the data to blast-furnace operation.

It is the purpose of the present paper to indicate in some detail the most obvious method of using the slag viscosity tables in slag control, and by actual illustrative examples to demonstrate the method. It is not considered necessary to reproduce the slag tables since the publication in which they appear can be readily obtained by any one desiring it.

Beforehand, it may be well to make clear exactly what significance is attached to the term "viscosity" and to point out how this property in the case of a slag is of primary importance in determining the economy

of operation of the blast-furnace. This last matter is of unusual importance at the present time. Whether or not there will be sufficient coke at the blast-furnaces during the winter of 1918-1919 is a matter of grave importance, but the most immediate duty of every blast-furnace superintendent is to make a maximum production of pig-iron with a minimum fuel consumption.

## VISCOSITY

All bodies may be divided into three classes—gaseous, liquid and solid. For our present purpose we will confine our attention to the solid and liquid states of matter. Here we will take our stand with the physicist rather than the chemist, and simply define a liquid as any substance other than a gas, which if left to itself will assume in the course of time the shape of a vessel in which it is placed; and a solid as a body which retains its own shape under the action of small forces. According to this definition a piece of slag at room temperature is a solid regardless of whether it is glassy, or "lean," or whether it is crystalline, or "limey." On the other hand, a slag is a liquid, whether the entire mass is homogeneous or contains numerous small crystals scattered through its interior, provided it will move, however slowly, along an inclined runner under the action of gravity. In all these cases, the chemist makes a number of distinctions in his definitions, well-suited for his own needs but of no value in the present case.

Having fixed in mind exactly what is meant by "solid" and "liquid," let us give our attention to the definition of viscosity. The viscosity of any substance is proportional directly to the force required to rotate a cylindrical rod of given dimensions with unit angular velocity when immersed in the liquid. As every one knows it takes a greater effort or force to twist a pole around in a barrel of pitch than it does in a barrel of water. If it takes a thousand times as much force in the former case than in the latter, the viscosity of the pitch would be a thousand times as great as that of water. In the absolute or C.G.S. system of units used in the slag tables (*Technical Paper* 187) it so happens that the viscosity of water at 20 deg. C. is almost exactly 0.01. Hence the viscosity of the pitch would be equal to 1000  $\times$  0.01, or 10 C.G.S. units.

Another way to visualize the property of viscosity is to recall that the length of time it takes a liquid of given volume to flow through a small capillary tube, under a constant pressure-head, is directly proportional to its viscosity.

While all liquids have a definite viscosity which can be measured, the viscosity of a solid is, of course, in-

<sup>4</sup>See also above.

finite. We may therefore define, a solid as a body the viscosity of which is infinite, and a liquid as a body, other than a gas, the viscosity of which is finite or measurable.

I have found that there exists in the minds of some a strange confusion regarding the meaning of viscosity. This is probably due to the ordinary meaning of the word "viscous" as used in conversation. Such a one is certain that molasses is "viscous" and has "viscosity"; but is at a loss when asked to compare it with water or ice, and may conclude that neither ice nor water have any viscosity. As has been stated, the viscosity of water at 20 deg. C. is equal to 0.01, while the viscosity of ice is infinitely great, i.e. greater than any value which we could assign to it.<sup>2</sup>

Just as the reciprocal of density is specific volume, so the reciprocal of viscosity is "fluidity." In other words, fluidity, as physically defined, is numerically equal to 1 divided by the viscosity. Accordingly, the fluidity of water at 20 deg. C. is  $\frac{1}{0.01}$  or 100; while the fluidity of the pitch would be  $\frac{1}{\infty}$ , or 0.1. It is obvious that the fluidity of a solid is equal to  $\frac{1}{\infty}$ , or zero. Just as there are no bodies with zero viscosity, so there are no bodies with infinite fluidity. Values expressed in terms of fluidity instead of viscosity offer certain advantages when plotted against temperature, forming very nearly a straight line function. However, it would appear that viscosity is actually the measurable property of a body, and for this and other reasons it was used exclusively in the slag tables.

#### CHANGE OF VISCOSITY WITH TEMPERATURE

The viscosity of practically all bodies decreases with rising temperature, and this rule is true without exception in the case of silicates and mixtures of silicates. The rate of change is most rapid just at the melting point. Above the melting point, i.e., the temperature at which the slag passes from the solid to the liquid state, some slags decrease in viscosity much more rapidly than others. The rate of change of viscosity at any given temperature is known as the temperature coefficient of viscosity. If we plot the temperature of the slag as abscissae and the viscosity as ordinates, we get in the case of a slag such a curve as is shown in Fig. 1, known as a temperature-viscosity curve. The line AB which the upper portion of the curve approaches asymptotically cuts the X-axis at a point corresponding to the melting point of the slag, since at that temperature the viscosity becomes infinite.

Even at temperatures well above the melting point the change of viscosity of practically all bodies is much greater than is ordinarily supposed. For instance, water just above the freezing point is about 3 times as viscous as water at 100 deg., the rate of change being about as rapid above 50 deg. as below it.

#### DEPENDENCE OF TEMPERATURE-VISCOSITY RELATIONS ON SLAG COMPOSITION

It will be sufficient here to state that the shape and position of the temperature-viscosity curve with respect to the axes is entirely dependent on the chemical composition of the slag as shown by analysis. Sometimes

a relatively minor change in the percentage of one or more of the major constituents—lime, alumina and silica—causes a great change in the temperature-viscosity relations as shown by the temperature-viscosity curve. This is due to the existence of undissociated molecular compounds of lime, alumina and silica in the molten state,<sup>4</sup> with fields of stability which are those indicated by the temperature-concentration diagram of this ternary system as given by Rankin and Wright.<sup>5</sup> If, for instance, we gradually increase the lime content of a slag the temperature-viscosity relations do not undergo a continuous, gradual change in the same direction, but display well-marked maxima and minima.

Contrary to the usual belief, changes in the percentages of the minor constituents of a slag—MgO, MnO,

FIG. 1.—VARIATIONS OF VISCOSITY WITH TEMPERATURE

FeO, TiO<sub>2</sub>, Na<sub>2</sub>O and K<sub>2</sub>O—have a practically negligible effect on the temperature-viscosity relations provided the percentages of the major constituents—CaO, Al<sub>2</sub>O<sub>3</sub>, and SiO<sub>2</sub>—do not change relatively to one another. In the slag investigations it was found that the temperature-viscosity relations of all slags in which the sum of the percentages of the minor constituents did not exceed 14 per cent were determined only by the relative percentages of lime, alumina and silica. This condition is met by practically all slags in which the percentage of MgO, the most important minor constituent, does not exceed about 8 per cent.

Sulphur in iron blast-furnace slags is present as calcium sulphide, CaS, and should be treated simply as one of the minor constituents. In slag analysis, sulphur should be reported as calcium sulphide, CaS.

The small effect exerted by the minor constituents on the slag properties is due to the fact that they are present in the slag in the state of solution, retaining

<sup>2</sup>For the evidence pointing to the existence of silicate compounds in the liquid state, see *Technical Paper 189*, pp. 7-10, 21-23, 29-33.

<sup>5</sup>For convenience in presentation the case of plastic solids, flow under shears greater than a critical value, etc., are not taken into consideration. For further information on these points see Bureau of Mines *Technical Paper 189*, pp. 10-12.

their oxide or sulphide structure. On the other hand, lime, alumina and silica are not present in the molten slag as a mutual solution of the oxides of calcium, aluminium and silicon, but as more or less complex silicates and aluminosilicates of lime. The identity and relative proportions of these silicates and aluminosilicates which are present in a slag can be readily calculated from the ternary diagram of Rankin and Wright, although, as has been previously pointed out, these investigators were not aware at that time that their data were applicable at temperatures above the saturation temperature of the melt. The presence of the minor constituents does not make itself felt appreciably until the concentration of one of them becomes great enough to result in the introduction of a new molecular species into the ternary system, changing it thereby to a quaternary system.

#### BEHAVIOR OF THE SLAG IN THE FURNACE

The blast-furnace is a furnace which operates on a regenerative principle, the highly heated gases of combustion passing up through the descending charge and pre-heating it. These gases of combustion, or flue-gases, are further used to pre-heat the air supplied for combustion, since they are high in carbon monoxide and fortunately have a fairly good calorific value.

The conditions are therefore such that if the furnace shaft were filled with coke alone the temperature would within a short while reach such a high value that the entire refractory lining of the furnace would be fused. However, if the coke is mixed with just the proper amount of material—the slag ingredients—which melts, say, at 1470 deg. and runs down into the hearth and thence through the iron notch to the outside, there will result a slow downward movement of the charge with the coke burning away at the same rate that the slag (and also molten iron) runs down into the hearth. This downward movement of the charge, initially at atmospheric temperature, is the factor which prevents the attainment of extreme temperatures in the smelting zone. It is seen then that the temperature-viscosity relations of the slag (which includes the phenomenon of melting) determines the working temperature of the blast-furnace. Like all industrial furnaces, the blast-furnace consumes an amount of fuel which increases rapidly as the furnace temperature is raised. It is upon this point that the importance of slag control as related to fuel economy hinges, and for this reason the slag problem is essentially a fuel problem.

The ternary eutectic of lowest melting point in the lime-alumina-silica system is point 2 in Rankin and Wright's diagram, having a melting point of 1165 deg. C., as determined by viscosity measurements,\* and corresponding to a composition 23.25 per cent CaO, 14.75 per cent  $Al_2O_3$ , and 62 per cent  $SiO_2$ . Therefore, as soon as a temperature of 1165 deg. C. is reached by the charge during its descent downward toward the hearth, a certain amount of this low-melting eutectic may be formed. However—and this is an important point—since this eutectic differs widely in its composition from that of the slag ingredients as a whole, and since it has with its high silica content an extremely high viscosity at all furnace temperatures, it is very probable that no formation of liquid slag sufficient to cause any appreci-

able downward movement of the slag occurs until a temperature is reached corresponding approximately to the melting point of the entire slag ingredients. At least, until there is available some experimental data on this subject, the above assumption is the simplest one that can be made.

Since with this assumption the melting point of a slag is equal to either point 5 or point 6 of Rankin and Wright's diagram, slag formation actually begins in the furnace at a temperature of either 1310 deg. C. or 1265 deg. C., these being the melting points respectively of these two ternary eutectics. The composition of point 5 is 38 per cent CaO, 20 per cent  $Al_2O_3$ , and 42 per cent  $SiO_2$ ; and of point 6 is 47.2 per cent CaO, 11.8 per cent  $Al_2O_3$ , and 41 per cent  $SiO_2$ .

When, after melting, the slag has its temperature raised to such a point as to flow around and entrap within it the molten iron globules, its metallurgical function in the blast-furnace may be said to have become operative. It is very probable that this initiation of its function as a desulphurizer and source of silicon corresponds more or less closely to a definite value of viscosity, placed tentatively at 10. It is doubtless preferable to assume that, instead of the molten slag flowing around the molten iron globules at the time when the viscosity of the former reaches a value of 10, the molten iron globules fall by gravity from a higher level into the viscous slag at a somewhat lower zone in the shaft and are imbedded therein or trapped therein by the motion of the molten slag. At any rate, the initiation of the desulphurizing process begins when intimate contact is made between iron globules and molten slag, whether the slag entraps the globules *in situ* or after the latter have moved a certain distance down the shaft.

On the other hand, measurements made on slags at flush indicate that the slag as it flows from the cinder notch has on an average a viscosity of 4.

We are concerned then chiefly with the temperature relations of the slag as it decreases from a viscosity of 10 to a viscosity of 4. This temperature interval, during which the important chemical reactions of silica reduction and desulphurization occur, may be appropriately termed the "active range" of the slag.

For the purpose of conserving coke, it should be the aim of the superintendent to keep this active range of the slag as low on the temperature scale as possible. If we leave out of consideration the black "scouring" slags containing a large percentage of iron oxide usually accompanied by undue irregularities in charge descent, it does not seem probable that in a furnace producing basic iron the operator can choose a slag having too low an active range. High sulphur in pig-iron is usually caused not by the fact that this range is too low, but that the range is too narrow, affording no flexibility and allowing insufficient time for the iron globules to be in intimate contact with the slag.

As will be shown later it is possible, having given an ore or ore mixture to determine with the aid of slag viscosity tables that slag composition which will have the lowest practicable active range.

In using the tables, there are certain precautions which must be observed by the operator.

Since, for reasons advanced above, the minor constituents are not to be given consideration, it is necessary first to calculate all slag analyses to a basis of 100 per

\*See Technical Paper 189, p. 26. The melting point as determined by Rankin and Wright, using the crystallographic method of quenched melts, is 1170 deg. C.  $\pm$  5 deg.

cent lime, alumina, and silica. In this way, all possible slag compositions can be expressed in terms of the three constituents of the ternary system  $\text{CaO-Al}_2\text{O}_3\text{-SiO}_2$ . The temperature-viscosity relations of all slags is simply a function of two independent variables, alumina and lime, or alumina and silica, or lime and silica. Obviously, the percentage of the third constituent is fixed as soon as the percentages of the first two constituents are known. This arithmetical calculation must be made whenever a slag is to be referred to the slag viscosity tables, so that it will be advisable to indicate the necessary procedure.

Let us consider a slag which shows the following analysis:

|                               | Per Cent |
|-------------------------------|----------|
| CaO.....                      | 40.17    |
| $\text{Al}_2\text{O}_3$ ..... | 13.07    |
| $\text{SiO}_2$ .....          | 35.32    |
| MgO.....                      | 5.51     |
| CaS.....                      | 3.87     |
| Other oxides.....             | 2.06     |
|                               | 100.00   |

This particular slag represents average practice in the United States, according to analyses representing 44 per cent of the blast-furnace tonnage.

The calculation is as follows: The percentages of CaO,  $\text{Al}_2\text{O}_3$ , and  $\text{SiO}_2$  are added together, making a total of 88.56 per cent. The percentages of these three constituents are then multiplied each in turn by the factor

$$\frac{100}{88.56}$$

This gives as the composition of the slag: 45.36 per cent CaO, 14.76  $\text{Al}_2\text{O}_3$ , and 39.88  $\text{SiO}_2$ , a total of 100 per cent.

The operator who is in the habit of associating certain slag characteristics to a slag containing 12 per cent  $\text{Al}_2\text{O}_3$  and 36 per cent  $\text{SiO}_2$  by actual chemical analysis, must carefully avoid comparing such a slag with one of 12 per cent  $\text{Al}_2\text{O}_3$  and 36 per cent  $\text{SiO}_2$  as given in the tables without first recalculating the slag to a basis of 100 per cent lime, alumina, and silica. After this recalculation it is probable that this slag will be represented in the tables by a 13 per cent  $\text{Al}_2\text{O}_3$ , 39 per cent  $\text{SiO}_2$  slag.

While it may seem that emphasis on such a simple matter is unnecessary, it is just such minor points as this which will make the application of the tables appear at all unusual to an operator schooled to think only in terms of percentages by analysis without regard to the relative proportions of CaO,  $\text{Al}_2\text{O}_3$ , and  $\text{SiO}_2$ . Fortunately, this is a difficulty which is not serious.

As was explained in some detail in Bureau of Mines *Technical Paper 187*, the matter of obtaining a representative sample of slag at flush for chemical analysis is a difficult problem. A single sample will in no case give the correct average slag composition, and in some cases not even approximately so. Three samples, taken at the beginning, middle and end of each flush and a sample of the slag at cast will, when made into a well-mixed composite sample, yield a fairly good representative sample. The writer has several times witnessed a spirited discussion between a blast-furnace superintendent and a works manager over a supposed change in slag composition, amounting to several per cent  $\text{SiO}_2$ , which discussion resulted in a change in the charge, when two samples taken during the same flush showed more than 2 per cent difference in their  $\text{SiO}_2$  content. The best method of combating this operating difficulty is obviously to take as frequent slag samples as can be handled by the analytical staff at the works, and if the results obtained in this way justify a further increase

in the number of samples, to increase the number of analysts.

Mention has also been made of the errors which are often found in works analyses of slags, due to the common practice of dissolving the sample in hydrochloric acid, instead of analyzing according to the accurate method of fusion with sodium carbonate. The error introduced by the former method is greater in the case of slags high in alumina than in low alumina slags, although even a moderate alumina content may cause serious difficulty. This source of inaccuracy should be given careful consideration by every blast-furnace chemist, and corrected where found to be prevalent. In most cases, lime, CaO, is not determined as such in the analysis of the slag, but is obtained "by difference," and includes other oxides such as  $\text{Na}_2\text{O}$ ,  $\text{K}_2\text{O}$ ,  $\text{TiO}_2$ , and sometimes MgO and MnO where these two oxides are not separately determined. In addition, this expedient, used for the sake of saving time, throws the sum of all the analytical errors into the CaO percentage where, more than anywhere else, an accurate value is required on account of the fact that the slag properties are peculiarly susceptible to small changes in the lime content.

The operator must therefore at the outset eliminate the above-mentioned difficulties of slag sampling and analysis, or at least reduce them to a minimum, before he is in a position to derive the greatest benefit from the application of the slag tables.

#### THE SLAG VISCOSITY TABLES

In Bureau of Mines *Technical Paper 187* are given the complete slag tables, showing the viscosity in C.G.S. units of iron blast-furnace slags for even percentages of alumina between 7 and 24 per cent; over a wide lime-silica range; for temperatures of 1350 deg. C. (2462 deg. F.), 1400 deg. C. (2552 deg. F.), 1450 deg. C. (2642 deg. F.), 1500 deg. C. (2732 deg. F.), 1550 deg. C. (2822 deg. F.), and 1600 deg. C. (2912 deg. F.); and also the temperatures at which the different slags have viscosities of 2, 4, 6, 8, 10, and 12 C.G.S. units.

The tables cover a definite portion of the ternary system  $\text{CaO-Al}_2\text{O}_3\text{-SiO}_2$ , being confined to the stability fields of calcium metasilicate and gehlenite (see *Technical Paper 187*). This particular portion of the ternary system was selected after examination of the relative proportions of lime, alumina, and silica in a number of slags representing widely different practices.

The range of slag composition included in the tables is as follows:

#### RANGE OF COMPOSITION INCLUDED IN SLAG VISCOSITY TABLES (Calculated to Basis of 100 per cent CaO, $\text{Al}_2\text{O}_3$ , $\text{SiO}_2$ )

| $\text{Al}_2\text{O}_3$<br>Per Cent | $\text{SiO}_2$<br>Per Cent | CaO<br>Per Cent | $\text{Al}_2\text{O}_3$<br>Per Cent | $\text{SiO}_2$<br>Per Cent | CaO<br>Per Cent |
|-------------------------------------|----------------------------|-----------------|-------------------------------------|----------------------------|-----------------|
| 7                                   | 50-43                      | 43-50           | 16                                  | 48-35                      | 36-49           |
| 8                                   | 50-43                      | 42-49           | 17                                  | 47-33                      | 36-50           |
| 9                                   | 49-42                      | 42-49           | 18                                  | 46-32                      | 36-50           |
| 10                                  | 49-42                      | 41-48           | 19                                  | 45-31                      | 36-50           |
| 11                                  | 49-42                      | 40-47           | 20                                  | 42-30                      | 28-50           |
| 12                                  | 49-40                      | 39-48           | 21                                  | 42-29                      | 37-50           |
| 13                                  | 49-39                      | 38-48           | 22                                  | 40-28                      | 38-50           |
| 14                                  | 48-37                      | 38-48           | 23                                  | 38-28                      | 39-49           |
| 15                                  | 48-36                      | 37-49           | 24                                  | 39-28                      | 37-48           |

It is true that a small number of furnaces are run on a dolomitic or high magnesia flux, in which cases the percentage of MgO in the slag will be well above 8 per cent, which is the upper limit fixed for the direct application of the viscosity data given in the tables. The relative importance, however, of this practice has not

yet seemed sufficient to warrant a systematic investigation of the quaternary system  $\text{CaO-MgO-Al}_2\text{O}_3\text{-SiO}_2$ . This problem will doubtless be solved, nevertheless, in the not distant future. Since the practicability of smelting to advantage titaniferous iron ores unusually high in  $\text{TiO}_2$  has been demonstrated by Auguste Rossi, it is probable that the quaternary system  $\text{CaO-Al}_2\text{O}_3\text{-TiO}_2\text{-SiO}_2$  will also ultimately demand attention at the hands of investigators.

#### SLAG CONTROL

With a given supply of raw materials—ores, coke, and limestone—the attainable economy in coke consumption is, for a specified grade of iron, chiefly dependent upon the maintenance of a proper slag composition. In the discussion of furnace operation which follows it has been convenient for the sake of brevity to assume that the reader is familiar with the salient features of pig-iron manufacture as given in the various text-books. In even a cursory study of this important industrial process it becomes evident to most readers interested in the subject that the question of the choice of slag composition has hitherto been entirely arbitrary on the part of the superintendent. In his decision he has been guided by previous furnace records and by his own experience. Nevertheless, he is called upon almost daily to meet unusual operating problems where his course of action is the combined result of intuition and shrewd conjecture. In the majority of cases such action involves a change in slag composition due to altering the composition of the charge, increasing or decreasing the burden, or both. The blast-furnace superintendent's task is at best a difficult one, and it becomes increasingly complex when furnace operations are interrupted or made irregular by such contingencies as a shortage of coke or other raw materials.

It is common in text-books to see a chapter on slags open with such a statement as, "It is required to make a slag of the following composition: 50 per cent  $\text{CaO}$ , 15 per cent  $\text{Al}_2\text{O}_3$ , and 35 per cent  $\text{SiO}_2$ ." There are certain inherent objections to such a statement. The most cogent is that the purpose of a blast-furnace is not to produce a slag of a definite composition, but on the contrary to produce iron of a definite grade, and what is more to the point, from a limited selection of ores. Probably no possible combination of his ores would enable an operator to attain a slag of such a composition as that "required" above. His problem is to utilize the ores on hand to the best advantage regardless of his personal or acquired slag preferences and with a minimum coke consumption.

#### ILLUSTRATIVE EXAMPLES TAKEN FROM PRACTICE

It is the chief purpose of this paper to point out (1) how an operator can determine what change in his charge should be made when an undesirable slag is being produced, and (2) how he can decide with the help of the slag tables, what is the "desired" slag corresponding to any given ore or ore mix, limestone, and coke. Both of these conditions can be arrived at by a purely mechanical procedure in which the personal equation of the operator is reduced to a minimum importance. A few examples taken from practice may illustrate the use of the slag tables.

The slag is making off-grade iron, high in sulphur, is chilling the furnace, i.e., running with difficulty from

the cinder notch. The slag shows by analysis the following composition:

|                               | Per Cent |
|-------------------------------|----------|
| $\text{CaO}$ .....            | 42.51    |
| $\text{Al}_2\text{O}_3$ ..... | 13.28    |
| $\text{SiO}_2$ .....          | 32.77    |
| $\text{CaS}$ .....            | 4.02     |
| $\text{MnO}$ .....            | 5.50     |
| $\text{MnO}$ .....            | 1.20     |

Re-calculating to a basis of 100 per cent lime, alumina, and silica we find the relative proportions of these oxides are:

|                               | Per Cent |
|-------------------------------|----------|
| $\text{CaO}$ .....            | 48.00    |
| $\text{Al}_2\text{O}_3$ ..... | 15.00    |
| $\text{SiO}_2$ .....          | 37.00    |
| Total .....                   | 100.00   |

Referring to the slag tables, we see that the temperature-viscosity relations of this slag and those of the compositions immediately around it clearly indicate the presence of too much  $\text{CaO}$ . These values, taken from the tables, are given below in Table I.

TABLE I.

| $\text{Al}_2\text{O}_3 = 15$ Per Cent<br>Per Cent | $\text{CaO}$ | Active Range<br>Temperature at Which |                           | Width of<br>Active<br>Range<br>Deg. C. |
|---------------------------------------------------|--------------|--------------------------------------|---------------------------|----------------------------------------|
|                                                   |              | Viscosity = 4<br>Deg. C.             | Viscosity = 10<br>Deg. C. |                                        |
| $\text{SiO}_2$                                    |              |                                      |                           |                                        |
| 40                                                | 45           | 1,453                                | 1,346                     | 107                                    |
| 39                                                | 46           | 1,470                                | 1,366                     | 104                                    |
| 38                                                | 47           | 1,525                                | 1,394                     | 131                                    |
| 37                                                | 48           | 1,594                                | 1,448                     | 146                                    |
| 36                                                | 49           | > 1,640a                             | 1,568                     |                                        |

a The symbol > signifies "greater than."

An examination of Table I shows that, while the width of the active range is sufficient, the slag demands an abnormally high furnace temperature in order to flow easily from the cinder notch, i.e., 1594 deg. C., and also that a slight increase in lime, due to many of the unavoidable irregularities in the charge would give a slag ( $\text{CaO} = 49$ ,  $\text{SiO}_2 = 36$ ) which is much too refractory, for satisfactory operation.

It is a well-known fact that extremely high-sulphur irons are most often met with in basic practice where a high percentage of lime is present in the charge. When any unavoidable fall in blast temperature occurs or when the descent of the charge is irregular or delayed, portions of the descending limey slag pass over quickly to the solid state, capable of acting chemically upon the pig iron very slowly if at all, in so far as desulphurization is concerned. In other words, the melting point of the slag lies dangerously near the temperature of the smelting zone. To maintain a furnace temperature sufficiently high to avoid this difficulty would call for an unreasonably high coke consumption and a short life of furnace lining. There appears to be considerable evidence that in basic practice many furnacemen entail an unnecessarily high coke consumption simply because they make use of a very limey slag where a less limey slag would produce an iron as low in sulphur and with the proper silicon content at a lower furnace temperature.

In the case above, the lime content of the slag (referred to 100 per cent lime + alumina + silica) could advantageously be lowered from 48 to 45 per cent. If any further difficulty was experienced due to a too hot or a too cold furnace, it could be ascribed logically to excessive or insufficient coke, and the necessary change made in the burden.

This illustrates in a general way how the tables may be used in helping to solve a slag problem which, unless successfully solved, might mean a shut-down.

It would be both interesting and profitable for the superintendent who has access to past furnace records

of pig and slag analysis and coke consumption to compare the conclusions drawn from data given in Table I for a number of slags with the actual results obtained. Unfortunately, in a large percentage of cases this is not feasible since the analysis of the slag does not include a determination of CaO as such, but only "lime" by difference.

Turning now from the case of the operator who is confronting the problem of avoiding a shut-down or continued off-grade iron due to improper slag composition, let us give our attention to the question of the initial decision as to the proper charge composition. This can be reached very conveniently by means of the slag tables, without making use of any rules-of-thumb or other maxims the applicability of which may be doubtful.

We will examine the most desirable slag practice using a mixture of equal parts of soft and semi-hard Tennessee ores, having the following composition:

|                                | Per Cent |
|--------------------------------|----------|
| Fe                             | 42.8     |
| SiO <sub>2</sub>               | 24.3     |
| Al <sub>2</sub> O <sub>3</sub> | 3.8      |
| CaO                            | 2.1      |

The coke contains 5 per cent SiO<sub>2</sub> and 3 per cent Al<sub>2</sub>O<sub>3</sub>. Let us assume a basic iron product containing 1 per cent Si and 94 per cent Fe.

Each pound of ore yields  $\frac{0.428}{0.94}$  or 0.455 pounds of pig iron. For 1 pound of pig iron produced it is necessary to flux  $1 \times \frac{0.243}{0.455}$  or 0.534 pound of SiO<sub>2</sub> and  $1 \times \frac{0.038}{0.455}$  or 0.083 pound of Al<sub>2</sub>O<sub>3</sub>. To these amounts, assuming a fuel consumption of 2240 pounds of coke per ton of pig iron, must be added, respectively, 0.05 pound SiO<sub>2</sub> and 0.03 pound Al<sub>2</sub>O<sub>3</sub>, making a total of 0.584 pound SiO<sub>2</sub> and 0.113 pound Al<sub>2</sub>O<sub>3</sub> per pound of pig iron. Since the pig iron contains 1 per cent Si, equivalent to 0.021 pound SiO<sub>2</sub> per pound of pig iron, this amount must be deducted from the available SiO<sub>2</sub>, leaving a balance of 0.563 pound SiO<sub>2</sub> per pound of pig iron.

Assuming that we charge pure limestone (100 per cent CaCO<sub>3</sub>) or a stone which contains no alumina or silica, and that the burden ratio was not changed, the ratio of silica to alumina in the slag would be equal to  $\frac{0.563}{0.113}$  or 4.98, regardless of how much limestone is charged. Taking this ratio for the present as constant and equal to 4.98, it is possible to calculate directly the possible slag compositions corresponding to varying amounts of limestone charged.

Let  $x$  = per cent of CaO  
 $y$  = per cent of SiO<sub>2</sub>  
 $z$  = per cent of Al<sub>2</sub>O<sub>3</sub>

$$\text{Then } y/z = 4.98 \quad (1)$$

$$x + y + z = 100 \quad (2)$$

Assuming that the proper slag will contain between 38 and 50 per cent CaO, we first substitute the value 38 for  $x$  in equation (2).

$$\text{Then } y + z = 100 - 38 = 62 \quad (3)$$

$$\text{From (1) } y = 4.98 z \quad (4)$$

Substituting (4) in (3), we have

$$5.98 z = 62$$

$$\text{or } z = 10.3 \text{ per cent Al}_2\text{O}_3.$$

Hence,

$$y = 100 - (38 + 10.3) = 51.7 \text{ per cent SiO}_2.$$

Repeating this calculation for the remaining percentages of CaO between 38 and 50 per cent, we obtain the set of composition shown in Table II. There is also given opposite these compositions the temperatures at which these slags attain a viscosity of 4 and 10, indicating the position of the active range, obtained by referring to the slag tables.

TABLE II.

| Percentage Composition |                                |                  | Active Range—<br>Viscosity = 4 Viscosity = 10 |         | Width of                |
|------------------------|--------------------------------|------------------|-----------------------------------------------|---------|-------------------------|

(a) Solidifies at 1310 deg. C.

As is obvious the calculation of the compositions given in Table II can be performed graphically with great ease after the composition of the first and last members of the series is known, since the various percentages are all linear functions of one another.

An examination of the temperature-viscosity relations of the possible slag compositions as shown in Table I does not disclose any pronounced minimum active range, nor is the active range raised by increasing lime, at least up to 49 per cent CaO, but on the other hand it is lowered thereby.

Regarding the possible temperature-viscosity relations of those compositions not in the tables, it can safely be said that a slag containing a higher percentage of lime than is given in the tables is unsuitable for proper and economical furnace operation. Such a slag lies in the stability field of calcium orthosilicate, and has a melting point which increases with astonishing rapidity with increasing lime. Probably "liming up" of a furnace is usually due to the presence of such a slag whose composition lies in the orthosilicate stability field (see Fig. 1, Bureau of Mines *Technical Paper* 189). It may be concluded then that although the active range of the slags shown in Table II is lowered by increasing lime up to 49 per cent CaO, any further increase in lime will produce a slag of unusually high melting point and therefore undesirable. From the table it is also seen that for 49 per cent CaO the width of the active range has been considerably reduced, and that for both 48 and 49 per cent CaO the slag is characterized by that peculiar property, found only in low alumina slags, of solidifying sharply from a fairly fluid melt.<sup>7</sup> It is, of course, desirable to get away from such a condition, so that the operator in choosing his slag will select a somewhat less "limey" slag, say with 44 per cent CaO, 9.3 per cent Al<sub>2</sub>O<sub>3</sub>, and 46.7 per cent SiO<sub>2</sub> having a viscosity of 4 at 1490 deg. C. and a viscosity of 10 at 1369 deg. C.

Suppose the limestone showed from analysis the following: 48.50 per cent CaO, 3.25 per cent SiO<sub>2</sub>, and 1.20 per cent Al<sub>2</sub>O<sub>3</sub>.

It has been shown above that the amount of available SiO<sub>2</sub> in ore and coke which must be fluxed is equal to 0.563 pound per pound of pig iron, and of Al<sub>2</sub>O<sub>3</sub> is

<sup>7</sup>See Bureau of Mines *Technical Paper* 189, pp. 27-28.

0.113 pound. Since we have decided to use a slag having 44 per cent of CaO (on a basis of 100 per cent lime, alumina, and silica), it is obvious that the weight of CaO which must be charged per pound of pig iron is equal to  $(0.563 + 0.113) \times \frac{44}{56}$  or 0.53 pound. But the CaO present in the ore, amounting to 2.1 per cent will yield  $\frac{0.021}{0.455}$  or 0.04 pound of CaO per pound of pig iron.

The amount of CaO to be charged as limestone is then equal to  $0.53 + 0.035 - 0.04 = 0.525$  pound per pound of pig iron, which amounts to  $\frac{0.525}{0.485}$  or 1.08 pound of limestone per pound of pig. In the preceding calculation, the value 0.035 represents the number of pounds of lime per pound of pig which must be charged to combine with the sulphur of the charge to form calcium sulphide, CaS. This is based on an assumed percentage of 3.8 CaS in the slag.

It is of interest now to calculate what effect the failure to consider the silica and alumina in the limestone had in so far as their effect on the silica-alumina ratio was concerned. The amount of silica in the limestone per pound of pig is  $0.53 \times 0.0325$  or 0.017 pound, increasing the available SiO<sub>2</sub> from 0.563 to 0.580; while the amount of alumina is  $0.53 \times 0.012$  or 0.006 pound, increasing the alumina from 0.113 to 0.119. The revised

silica-alumina ratio is then  $\frac{0.580}{0.119}$  or 4.87, instead of 4.98. This difference may, in this case, be neglected for practical purposes in deciding upon the proper slag composition. Its effect on the lime charged, however, has been taken into account.

It may possibly be advisable when using a limestone unusually high in alumina or silica first to revise the silica-alumina ratio. This can be done in all cases with a high degree of accuracy by first assuming the slag to contain 45 per cent CaO, and then making the correction as shown above from a knowledge of the stone analysis. After this is done the procedure used in arriving at the data given in Table II is the same as was used.

We will consider in conclusion the case of a Lake ore of the following composition:

|                                        | Per Cent |
|----------------------------------------|----------|
| Fe, .....                              | 55.4     |
| SiO <sub>2</sub> , .....               | 6.8      |
| Al <sub>2</sub> O <sub>3</sub> , ..... | 1.6      |
| CaO, .....                             | 0.3      |

Using the same coke analysis previously given and assuming a fuel consumption of 1800 pounds of coke per ton of pig, calculations made in a manner similar to those in the case of the Tennessee ore mixture will, for a basic iron containing 1 per cent Si and 94 per cent Fe, furnish the data given in Tables III and IV. Here, however, the calculations have been extended to include the revised silica-alumina ratio mentioned above, for a limestone of the composition already stated.

TABLE III.

|                                                            |       |
|------------------------------------------------------------|-------|
| Lb. pig iron per lb. ore                                   | 0.589 |
| Lb. SiO <sub>2</sub> from ore per lb. pig                  | 0.115 |
| Lb. Al <sub>2</sub> O <sub>3</sub> from ore per lb. pig    | 0.027 |
| Lb. SiO <sub>2</sub> from coke per lb. pig                 | 0.040 |
| Lb. Al <sub>2</sub> O <sub>3</sub> from coke per lb. pig   | 0.024 |
| Lb. SiO <sub>2</sub> , reduced to Si                       | 0.021 |
| Lb. SiO <sub>2</sub> from stone (assuming 45% CaO in slag) | 0.013 |
| Lb. Al <sub>2</sub> O <sub>3</sub> from stone              | 0.004 |
| Lb. SiO <sub>2</sub> , available for slag                  | 0.147 |
| Lb. Al <sub>2</sub> O <sub>3</sub> , available for slag    | 0.055 |
| Revised silica-alumina ratio                               | 2.7   |

| 42                     | 15.7                           | 42.3             | 1.508                 | 1.390                  | 118                            |
| 43                     | 15.4                           | 41.6             | 1.498                 | 1.383                  | 115                            |
| 44                     | 15.1                           | 40.9             | 1.474                 | 1.361                  | 113                            |
| 45                     | 14.9                           | 40.1             | 1.453                 | 1.346                  | 107                            |
| 46                     | 14.6                           | 39.4             | 1.458                 | 1.364                  | 94                             |
| 47                     | 14.3                           | 38.7             | 1.506                 | 1.388                  | 118                            |
| 48                     | 14.0                           | 38.0             | 1.618                 | 1.432                  | 186                            |

In Table IV a well-defined minimum active range is noted at 45 per cent CaO. For basic iron, therefore, this slag composition is indicated, although for foundry iron a higher furnace temperature, corresponding to 42 or 43 per cent CaO, might be advantageously used. Adhering, however, to the question of basic iron, it is readily calculated that the weight of CaO needed per pound of pig iron is equal to  $0.202 \times \frac{45}{55}$  or 0.165 pound. The lime present in the ore, amounting to 0.3 per cent, will yield  $\frac{0.003}{0.589}$  or 0.005 pound CaO per pound of pig iron. Assuming, as before, that 3.8 per cent CaS is present in the slag, it is readily calculated that the amount of limestone which should be charged is equal to  $\frac{0.165 + 0.012 - 0.005}{0.485}$  or 0.355 pound per pound of pig.

## CONCLUSIONS

It seems reasonable to conclude that the slag-viscosity tables are destined ultimately to become as useful to the metallurgist and blast-furnace operator as the steam tables are at present to the mechanical engineer, although this does not preclude the possibility of their being revised and expanded from time to time.

It remains for each individual furnaceman to make the greatest possible use of the information contained in the viscosity tables.

It is not unreasonable to conclude that viscosity measurements similar to those already made on iron blast-furnace slags will be performed in the case of both copper and lead slags with the same relative measure of successful industrial application.

The dependence of fuel economy on the maintenance of the proper slag composition has not been elaborated in the present paper. It is a fact so well-known to metallurgists that it hardly requires any explanation. With this in mind, it becomes clear that, aside from any question of increased pig-iron production, an intelligent slag control in the blast-furnace is a most important step toward enormous savings in our available coal supply.

## Electric Welds

### Notes on Welding Machinery, the Properties and Microscopy of the Welds and a Peculiar Occurrence of Widmanstättian Structure

By ERNEST EDGAR THUM

WITH the advent of high-power electric welding machines both for spot and butt welding, an increasingly large number of joints are being made in this manner. Special machines have been developed for butt-welding of various shapes ranging from the smallest wire to heavy tires; for the manu-

voltage from about two to ten volts and perhaps as many thousand amperes, and then passing this heavy amperage through the pieces to be welded while they are pressed tightly together with the joint about midway between the gripping vises. In comparison with the rest of the secondary winding, these pieces of

FIG. 1.—ELECTRIC BUTT WELDER

facture of teapot spouts, all sorts of enameled ware, tubes and pipe. Spot welding machines of various sizes are also in operation, which instead of welding a continuous seam will fasten two or more plates together at isolated spots, making a joint much after the style of a riveted connection.

#### ELECTRIC WELDING MACHINES

The usual butt welder (Fig. 1) consists of a suitable pair of heavy copper clamps or vises for holding the work. One of these clamps is attached to a fixed and one to a sliding head, the latter of which can be moved toward the other with considerable force during the welding operation by manual operation of a compression lever. The work to be welded serves as part of the secondary circuit of an alternating current transformer, built into the base of the machine. This secondary usually has but one turn, a heavy water cooled copper bar bent up and ending in the vises mentioned above. The primary winding will contain fifty or more turns, depending upon the voltage of the power line and the voltage required to overcome the resistance of the pieces to be welded.

The operation of the machine, therefore, involves drawing a few kilowatts of electric power from a suitable supply, transforming it into a current ranging in

FIG. 2.—UPSET WELD

FIG. 3.—FLASH WELD

material to be welded have a small cross section and high specific resistivity; the passage of the current is consequently attended by the development of a large amount of heat at the joint, where the pieces rapidly attain a very high temperature. The constant pressure applied through the clamping arms forces the two together as the softening or welding temperature is attained, upsetting a considerable amount of plastic metal

FIG. 4.—SPOT WELDER BUILDING LATTICED FRAMES

as in Fig. 2, or, if the pressure and current are held a longer time, extruding considerable burned metal in the form of a perpendicular fin (Fig. 3). The current is now shut off, the piece cooled and annealed (if the latter operation is thought necessary), and the weld is completed by grinding off the fin.

## SPOT WELDING

The operation of the spot welder is in no wise different. As shown in Fig. 4, the gripping vises are replaced by heavy copper dies or electrodes which close upon the sheets to be welded. The current is switched on and heats intensely the metal throughout a small region between the copper terminals, and the sheets are welded over a roughly circular spot. Extrusion of metal in this case is prevented by the continuous lateral support which the cold sheet affords the heated area; however, a small crater-like depression is formed by the pressure of the die upon the plastic metal (Fig. 5).

A welding operation may be regarded merely as a process of bringing the particles of two separate pieces of material within the region of their mutual molecular attraction either by means of heat (increasing their plasticity) or by pressure (increasing their proximity) or by both heat and pressure. If time and sufficiently close contact is afforded, the molecules of the one piece migrate into the other even in the cold and form an alloy at that point. It follows that the making of an electric weld is an exactly similar operation to that of welding on an anvil. The great advantage lies in the efficient method of producing the heat electrically, and the pressure mechanically. This results in an enormously increased speed of operation, and indirectly it eliminates the formation of undesirable metallic oxides on the heated surface which are so troublesome to the blacksmith. This is due to the fact that the heating is done so much more rapidly than in the forge, out of contact with the heated air blown through a bed of

FIG. 5.—SPOT WELD JOINING TWO STEEL SHEETS

coals, and withal so quickly and efficiently that only a small amount of oxide is formed, and this is immediately eliminated in the fin of hot metal squeezed out from the welded zone.

## WELDING HIGH SPEED TOOLS

Shortly after the outbreak of the war, speculation in metals forced the price of high speed or tungsten steels for machine tools to such an exorbitant figure that an ordinary lathe tool became a piece of precious metal, difficult to procure at any price. Many plants resorted to the expedient of spot welding a small inset of high speed steel into a notch cut in the end of a carbon steel tool (Fig. 6). This was a very economical

procedure, inasmuch as the welding operation is quite inexpensive, and the stub end of an old lathe tool of high speed steel too short for the holder could be cut up and used to make the working edge of several standard size tools.

Considerable trouble was experienced, however, from the tendency of the high speed inset to break off, cracking through at a short distance above the welds.<sup>1</sup>

FIG. 6.—LATHE TOOL WITH CUTTING POINT OF HIGH SPEED STEEL

A microphotograph of the weld showed very little interpenetration of the two metals, the alloy which was formed at the junction by the welding current being about 0.0006 inch in thickness.

The troubles following welding of high speed steel resembled the familiar "season cracking" of bronzes. These latter cracks probably result from failure along surfaces which are under initial stresses (set up, in the case of brass and bronze, by cold working). The strains resulting from these stresses are usually beyond the power of direct observation under the microscope, and no evidences of structural weakness could be observed in the steel inset, even though studies of low carbon welds showed considerable evidence of slip bands, as will be seen in what follows.

It was found, however, that cracking in service could easily be eliminated by placing the tool in a hot oven immediately after welding, before the piece had a chance to cool, and annealing to a dead soft state by cooling in lime, later hardening and tempering the tool in the proper manner. The time at the annealing temperature was apparently sufficient to allow the molecules which were strained in some manner during welding to adjust themselves to the orientation required for stability at low temperatures.

## WELDING HIGH CARBON STEELS

In order to throw some light upon the chemical and physical changes induced by the welding process, pieces of 0.97 per cent carbon drill steel, of  $\frac{3}{8}$ -inch diameter, were studied after butt welding. Test pieces of the original stock and of both annealed and unannealed welds were made by mounting in a lathe, removing the excess metal of the fin, and then turning or grinding a short length of the bar accurately to a diameter of one-half inch, with the weld in the center of the turned portion. In the unannealed welds, the turned portion was but one-half inch in length in order that the failure would be forced to occur within the portion of the bar altered in constitution by the welding heat. Tension tests of the unannealed welds showed, in all cases, a

<sup>1</sup>The writer investigated this and other phenomena attending electric welding for the Thomson Electric Welder Company of Cincinnati during 1916, and through their courtesy is enabled to present the more interesting results of his examinations.

failure with little or no necking occurring at the end of the turned portion—that is to say, farthest from the weld and in the softest portion of the test piece. The strength thus developed was much higher than even the strength of the original steel, and it is clearly evident that all parts of this weld have a higher ultimate strength than the original bar. The average results of the tension tests follow:

| Material                | Ultimate Strength<br>lb. per Sq. In. | Contraction<br>in Area,<br>Per Cent | Elongation<br>in 1 in.,<br>Per Cent |
|-------------------------|--------------------------------------|-------------------------------------|-------------------------------------|

### ANNEALED WELDS

In the annealed bars failure always occurred at the weld, accompanied by considerable necking, strictly limited to the close proximity of the point of failure. The marked increase in ductility of the steel at the weld suggested the possibility of a very considerable change in carbon content at that point. Metallographic examination substantiated this suspicion—eye examination of a polished surface showed a zone some one-eighth of an inch long which etched much lighter than the boundaries, and under the microscope exhibited primary ferrite in pearlite. Fig. 7 shows a micrograph of the edge of this decarbonized zone, indicating an unmistakable variation in carbon content from the eutectoid stock at the left toward the decarbonized weld. Conviction became certainty upon analyzing saw dust from cuts through the weld and through the stock; the former gave 0.57 per cent and 0.51 per cent for two different welds, while the original stock returned 0.97 per cent carbon.

An explanation of this variation of the carbon content is not apparent. The welding current is on but a few seconds; for the matter of a second or thereabouts the temperature is so high that considerable iron is burned in the plastic material squeezed out by the pressure, but then the current is immediately interrupted and the piece rapidly cools. Undoubtedly a small amount of iron oxidizes at the surface to be welded, but this is entirely extruded, no oxides of iron nor blowholes of carbon monoxide being observed in any section. Again, the axis of the bar—which while the hottest, is also the furthest from the atmosphere—evidences the maximum amount of decarburization. How a weld can be made without blowholes, or how a piece of steel can be decarbonized without the deleterious effects attending so-called "burning" are points yet to be investigated.

Some microscopic examinations gave hints of a carbon migration away from the welded spot back into the unaffected stock. However, the problem of demonstrating a high carbon zone between the weld and the stock was attacked by a senior student at the University of Cincinnati with negative results. One hardly conceives the existence of a driving force during this operation capable of transporting carbon any great distance in the few seconds a butt weld is at a reasonably high temperature, and yet the speed of penetration of oxygen into the steel and carbon monoxide outwardly appears incredibly rapid. Numerous gas cavities, on the other hand, form readily when spot welding rusty structural steel.

### UNANNEALED WELDS

The unannealed weld in eutectoid steel furnishes a perfect specimen for metallographists. The thermal gradient of the heated pieces rises sharply from slightly above room temperature at the vise to a maximum at the joint. In like manner, the axis of the rod is materially hotter than the surface. Just before the current is switched off, an ellipsoidal-shaped core of well defined boundaries has been heated to and beyond the critical temperature with the result that within this zone the steel is then austenitic, that is to say, the iron carbide is absorbed in solid solution; while just without these boundaries the steel has been annealed to the sorbitic state (or remains in the pearlitic condition, if that were the structure of the original bar). Fig. 8 shows the transition of a slowly cooled hypo-eutectoid steel at the left into the cloudy sorbite at the right, beautifully illustrating in one view the entire mechanism of cementite absorption.

Immediately upon interrupting the electric current, the austenitic core is "quenched," in that its surrounding cold and unaltered sheath abstracts heat very rapidly by conduction, with the result that the core exhibits every possible decomposition product between austenite and pearlite, regularly arranged in bands. The lines of demarcation are sometimes so clear that the naked eye can observe a dark band developed by the quick etching so characteristic of troostite. An instance of this is given in the micrograph shown in Fig. 9, where the lighter martensite on the right changes into the dark-etching spots of troostite on the left in a narrow zone bounded approximately by the width of the field.

Within the space of about twice the diameter of the piece, a weld before annealing possesses a core whose center exhibits nearly the maximum hardness attainable after quenching such a steel. Entirely surrounding this core are layers or muffs of similar form and definite boundaries which gradually change in hardness and toughness to that of the original stock—in case the latter was in a soft condition before welding. In welding hardened steels, on the other hand, the outer muff surrounding the core, being in the sorbitic condition, is liable to be softer than the stock. Barring the decarbonized zone, this entire alteration can be obliterated by proper annealing, after which the entire tool or any part of it can be given any requisite hardening or tempering.

The statement can be drawn from the above remarks that a welded bar, not heat treated, will break at some distance from the joint under static load, but at the weld if tested under sharp, eccentric impact. After heat treatment, the exact opposite will occur, as the joint will then be the weakest and most ductile part of the bar, due to a local decarburization.

### WELDING STRUCTURAL STEEL

In order to show a comparison, in a qualitative way, of the strength of a rivet as compared with that of a spot weld, four 3 x 8-inch bars were cut from 3-inch stock structural steel plate. Two of these were riveted together with two 3-inch rivets, one driven 1½ inches from either end; while the other pair were spot welded at corresponding points with a machine designed to give a weld 2-inches in diameter. The bars were then

laid flat on end supports, bent through about 45 degrees by a concentrated central load, and sawed lengthwise throughout, cutting through the center of the connec-

tion. A sketch of the bars, Fig. 10, will best show the results—the bars riveted together slipped past one another shearing the rivet, while the bars welded together showed absolutely no movement at the ends, nor

FIG. 10—COMPARISON OF STRENGTH OF WELDED AND RIVETED JOINTS

tion. A sketch of the bars, Fig. 10, will best show the results—the bars riveted together slipped past one another shearing the rivet, while the bars welded together showed absolutely no movement at the ends, nor

did a microscopic examination of the weld show any indication of plastic yielding.

The stress acting on the neutral surface of a beam is one of horizontal shear, tending to move the upper and lower sections in opposite directions. The rivets in the above case were working under ideal conditions, and showed a perfect shearing failure.

The spot welds were working under exactly the same loading. However, in their case, the soft, low carbon rivet steel, working at a disadvantage in being under a considerable initial stress, is replaced by the hardened higher carbon structural steel, an integral part of the metal both above and below. In riveting, good metal is removed to make way for softer, while in welding,

a joint of harder and stronger metal is built up which is continuous with both the pieces connected.

A number of small pits were noticeable after sawing through the weld, an enlarged view of one of which is shown in the accompanying micograph, Fig. 11. The rounded black area at the left is the blow-hole, surrounded by a zone of light-colored ferrite, which in turn is backed by the hardened steel of unchanged carbon content, just indicated in the dark spot at the upper edge. This appearance is readily explained as follows: The sheets were taken from a stock pile and no attempt made to clean them of rust or scale before welding. At the time of welding, little chance was given for any extrusion of hot metal, owing to the continuous lateral support of the heated area; in this manner any impurity which originally existed on the surfaces of the plates would be trapped and retained. The temperature of the weld is sufficient to effect a double decomposition of the oxide of the scale and carbide of the pearlite, thus:

The gas remains as a bubble in the center of a plastic mass of decarbonized iron.

#### EUTECTIFORM STRUCTURE IN SPOT WELDS

A very peculiar structure appears to a greater or less extent in all the spot welded low-carbon steel plates, but was not observed in any of the butt welds examined. It was found best developed near the outer edge of the spot welded structural plates of Fig. 10 and is shown in Fig. 12, at 260 diameters. The parallel striations, somewhat wavy, suggest pearlite, which it evidently cannot be, since the original metal is ordinary structural steel, whose microsection gives the typical hypo-eutectoid appearance (Fig. 13). A spheroidal mass at the center of the welds shows the microstructure of Fig. 14, a darkened background with the excess ferrite just being precipitated toward the edges of the crystalline grains. This entire central area, which etches dark in general, and which has been hottest during welding, is bordered by the peculiar light-etching eutectiform structure of Fig. 12, and which has not been so hot. The transition is extremely narrow, as is shown in Fig. 15 of the structural steel, and less clearly in Fig. 16 of a higher carbon spot weld. In turn, the eutectiform area grades into the unaffected original stock less abruptly.

This structure resembles martensite very much and one is tempted to class it as such, especially since unannealed welds are quite hard, and since this eutectiform structure is found adjoining sorbite. It is possible that the rapid conduction of heat by the relatively large and cold areas surrounding a spot weld, chilled and hardened the localized heated area of the weld and at the same time produced an inter-strain in the weld region which assisted in the formation of the martensite. While it is true that the exact center of a butt-welded joint is often troostitic and surrounded by a shell of martensite, this martensite in turn grades into the original stock through the well-known decomposition series without the development of this peculiar structure, which apparently requires a higher specific pressure for its production. In all the spot welds where this structure was observed the carbon content was moderate; low-carbon steels would not be expected to develop

such large quantities of martensite nor would martensite be expected separating zones of sorbite and pearlite.

The markings within the borders of more than one crystalline area of Fig. 12 are notably straight and parallel, suggestive that the mass is one of very closely twinned metal, appearing like the structure shown in Fig. 17, which shows twinning striations in rock minerals. While so-called "annealing" twins are formed in steel by heating it above the transformation range after slight deformation, these crystalline entities so common in brass, for instance, show relatively broad parallel-sided strips crossing the crystal from boundary to boundary (Fig. 18).<sup>2</sup> Doubtless the local conditions of heat and pressure during the welding process might readily be such as to cause annealing twinning, but such are very rarely observed in alpha iron.

Narrow twins, such as these under investigation might prove to be, are known as Neumann bands (Fig. 19), but these are commonly thought of as being "mechanical" twins, that is, produced by shock in rigid metal rather than by squeezing the hot plastic metal between the dies of a spot welder. Neumanns are readily disclosed after etching, as are these markings, but the former are destroyed by heat above  $A_c$ , which temperature may easily have been exceeded in the weld, since the latter areas border a sorbitic structure.

#### X-BANDS AND SLIP BANDS

Certain aspects of Howe's X-bands (Fig. 20) show a noticeable resemblance to these markings under investigation. The X-bands occur on polishing and etching iron after a severe deformation. However, all the illustrations given in "The Metallography of Steel and Cast Iron" are of X-bands in ferrite, even though one infers from the text that they were also observed in 14-point steel. They appear before any heating has been applied—indeed, rest and temperature both obliterate them. It is probable that if any X-bands were formed early in the welding operation they would be healed during the heating near  $A_c$  and would not appear in a polished section taken some months later. Likewise, slip bands (Fig. 21) are ordinarily observed on deforming a polished surface, and the amorphous or twinned layers between the moving laminae are not sufficiently wide to reappear after repolishing and re-etching. Thus, while doubtless the strain under spot welding is sufficient to develop slip bands profusely, they could be expected to leave no trace after polishing and etching a specimen.

In the above discussion which successively eliminated the possibility that this peculiar eutectiform structure represents either annealing twins, mechanical twins, X-bands, or slip bands, it has been tacitly assumed that the various grain areas delineated in Fig. 12 by the ends of the parallel markings represent crystals of homogeneous metal. Since hypo-eutectoid steel of such low carbon content could not be expected to develop such large areas of pearlite, one naturally wonders what has caused the entire suppression of the carbonaceous areas so prominent in the center of the weld (Fig. 14) and in the original stock (Fig. 13). Entire decarbonization of this cool, surface zone resulting in pure ferrite is not likely, since a study of butt welds

<sup>2</sup>Figs. 17, 18, 19, 20, 21, 27, 28 and 29 are from Howe, "The Metallography of Steel and Cast Iron."

shows that decarbonization depends upon degree of heat rather than proximity to surface. Furthermore, the decarbonization at a blow-hole is not deep seated nor complete, as is very evident from an examination of Fig. 11. Unquestionably the original carbon is still

ward rapidly while the high-temperature lines shrink into nothingness with even greater speed. Evidently some particular zone between the outmoving and in-shrinking isotherms remain at about the same temperature for a comparatively long time. Fig. 25 shows

FIGS. 16—21, 26—29

there and any explanation of the nature of the structure represented by Fig. 12 must account for its apparent disappearance.

#### TEMPERATURE DURING WELDING

A study of the probable course of heating and cooling in the neighborhood of the spot welded zone may be useful at this juncture. Suppose the assembled plates to have been gripped by the welder dies and the current turned on. After a short time interval, say one-half second, the temperature gradient existing in the plates directly between the dies may be something like that sketched in Fig. 22. A few arcs carry the current across the narrow air gap, heating the metal intensely—locally to the fusion point. In the diagram two small arcs are shown, with a 1000-deg. isotherm back into the metal somewhat. The intense heat very rapidly radiates by conduction back into the metal, giving isotherms like that shown for 500 deg., the temperature gradient being steepest in the regions nearest the arcs. This radiating heat reinforces the Joule effect of the high amperage flowing through the iron resistance, and their combination forms a 100-deg. curve about as shown.

At the end of the next time interval, a number of localized arcs have effected the weld over a considerable area and the heat from the resistance offered by joint and metal have pushed the isotherms back to the approximate condition shown in Fig. 23. At the end of the third time interval the current is shut off, when the heat gradient is approximately as mapped in Fig. 24, since the weld is completed in a matter of a second or two. The hot interior, now robbed of its heating current, is rapidly quenched by its surrounding colder metal, the low-temperature isotherms still moving out-

this hypothetical condition at the end of the fourth time interval.

It is hardly necessary to sketch the location of the temperature lines further. Within a very few seconds the 500-deg. isotherm begins to contract and even the 100-deg. isotherm halts and reverses its direction, starting back to its origin. The main point is that there is formed a hot zone, flatly ellipsoidal in shape where the temperature is above the welding heat, and a larger, fatter ellipsoidal volume where the temperature has exceeded the transformation range momentarily or for some time. Immediately thereafter the hot center is "quenched" by radiation into the cold surroundings, the interior at a much higher rate than the outer fringe, which latter may well remain stationary in temperature for some time.

#### AUSTENITE CRYSTALS FAULT ALONG CLEAVAGE PLANES

The austenitic spheroid, being directly between the dies of the welding machine, is under considerable compressive stress, but is unable to flow any measurable distance owing to its uniform side support by relatively rigid metal. Extrusion of a fin as in a flash weld (Fig. 3) is evidently impossible, but the highly stressed crystals of austenite develop their characteristic octahedral cleavage planes exactly similar to those accompanying the surface slip bands appearing in a polished surface after its underlying metal has been severely strained. On cooling through the transformation range the austenite tends to precipitate its excess ferrite—each crystal rejects the solute to its boundaries, hence the ferrite tends to gather along the cleavage planes. Thus, the central portion of the weld as shown in Fig. 14 is largely of dark-etching troostite or sorbite, but close

examination shows a well defined hair-like precipitation of the excess ferrite fringing many of the allotriomorphic crystalline boundaries, and numerous very fine, white, parallel striations crossing at 60 deg. appear in one of the dark areas near the center of the original micrograph. Very definite "fringes" of larger parallel ferrite needles extending inward from the grain boundary are shown in Fig. 15, near the edge of the sorbitic zone.

Just outside the darker-etching zone (in the region of eutectiform structure) a peculiar conjunction of pressure and temperature evidently occurred. During welding the temperature passed the transformation range, and the pearlitic areas passed into austenite. Migration of carbide to equalize the carbon content of these original austenitic crystals must have been extraordinarily rapid. The austenite crystals were at the same time fractured along their octahedral cleavage by the compressive stress of the welding dies, exactly as indicated in the discussion of the underlying dark-etching areas, and on cooling, after the electric current had been interrupted, each little lamina bounded by the parallel cleavage planes acted as an independent crystal in expelling ferrite to its surfaces. Hence the ferrite marks the sub-microscopic cleavage planes; or rather, the thinnest plate of eutectoid remains at the nucleus of each crystalline lamina. After polishing and etching,

agglomeration of the thin plates into balls of less superficial area, which is the normal appearance of low carbon steel (Fig. 13).

#### WIDMANSTÄTTIAN STRUCTURE

Widmanstätten structure, cleavage structure, or more shortly W-bands (Fig. 26), were named in honor of their discoverer, who found them in meteorites over a century ago. W-bands appear often in steel castings, and according to Sauveur<sup>2</sup> the excess constituent of steels cooling rapidly through the transformation range will largely precipitate between the cleavage planes of the small octahedra composing each grain, "probably because the necessary time is denied for this excess constituent to reach the boundaries of the grains."

The eutectiform appearance has therefore been shown to be identical in nature with the W-bands—it consists of a concentration of excess ferrite along the octahedral cleavage of austenite. The straightness of the striations (extremely perfect in some grains) is indicative of crystalline cleavage, while in many small crystals intersections at 60 or 120 deg. may be observed. Indeed, toward the right of Fig. 12<sup>3</sup> one star-like burst of rays shows five of the six possible directions starting from one point. The W-bands developed in spot welding have little in common with the appearance of Widmanstätten structure as ordinarily illustrated (Fig. 26), but the

Fig. 25—Location of isotherms a very short time after welding is completed.

the eutectoid films etch dark as a series of straight lines crossing from boundary to boundary of the original crystalline entity. Evidently the process of extruding the ferrite from the original austenitic laminae was just completed when the cooling of the zone in question prevented the further molecular mobility necessary for the

close packed W-bands of Fig. 27 would appear quite similar on a lower magnification. Howe and Levy<sup>4</sup> observe the same general appearance in overstrained and

<sup>2</sup>"The Metallography and Heat Treatment of Iron and Steel," page 212.

<sup>3</sup>Beyond the edge of the half-tone and therefore not shown.

<sup>4</sup>Trans. A.I.M.E., Vol. 51 (1915), p. 881.

heated austenitic manganese steel (Fig. 28), caused by the same train of events, that is to say, first fracturing the original austenitic crystals of the quenched metal along their cleavage planes, and thus forming a multitude of new crystalline entities. Then on annealing below the transformation range, the sluggish austenite reverts slowly to beta and alpha iron, extruding the excess and now insoluble cementite to the cleavage—in other words, to the boundaries of each individual plate-like crystal. Further heating will agglomerate this extruded cementite into nodules as shown in Fig. 29 of such considerable size as to be indentified with certainty by differential etching.

#### PRACTICAL DEVELOPMENTS

Spot welding—two years ago a comparatively unknown process—has risen rapidly in favor, giving great promise of effecting enormous savings in money, time and labor in the fabrication of structural shapes, steel railway cars, and ships. In building structural members the plain pieces of plates, angles, and beams are clamped together in their proper relation and stitched together with a spot welder, one weld appearing in place of each rivet. The saving in templet-making, laying out, punching, reaming, and match assembly is obvious. In car bodies and crane runways especially, there are no rivets to work loose after the shaking impact and vibration of long service. The elimination of electrolytic corrosion between rivet and plate would be a determining factor in many cases which would decide in favor of a homogeneous spot weld.

The engineer will naturally pause, however, until sufficient and varied data have been accumulated to convince him that the new will not be inferior to the present method in strength and shock resistance. It is thought that the decarbonization and hardening effects occurring at the weld and so evident in the higher carbon steels will have little effect upon the efficiency of a mild steel connection.

### Japanese Copper Industry

The refining and manufacturing of copper forms the most important native metal industry in Japan, the exportation alone amounting to about 100,000,000 yen (\$49,800,000) per year. The classes of copper articles exported and imported for 1917 are given in the following table:

| Articles                | Exports      | Imports     |
|-------------------------|--------------|-------------|
| Ingot and slabs         | \$43,747,551 | \$1,791,428 |
| Plates and sheets       | 682,352      |             |
| Wire                    | 2,189,152    |             |
| Insulated electric wire | 1,559,457    | 25,454      |
| Manufactures            | 118,579      |             |
| Waste or old            |              | 136,566     |
| Other                   | 1,525,210    | 19,419      |
| Total                   | 49,822,301   | 1,972,867   |

The ingots and slabs are imported from Korea, which, while a part of the Japanese Empire, has a separate customs administration. The waste or old copper consists principally of copper coins imported from China. Submarine cables, chiefly imported from Great Britain, constitute the greatest part of the insulated electric wire imported. The remaining imports, therefore, classified under the heading of "other," do not amount to more than \$20,000 per year, and consist of small shipments of extra high grade wires, tubes, and miscellaneous articles. It can be readily seen that there is

not a large market in Japan for American copper manufactures.

At present, owing to the decreased orders from Russia and the fact that the United States and many of the allied countries have set a price on copper below that at which the Japanese producers are willing or able to sell, there are large stocks of copper on hand. The present price in Japan is around 63 yen per 100 kin, which comes to about \$23.60 per 100 pounds.—CONSUL ROBERT FRAZER, *Commerce Reports*.

### Preparation of Belt Dressings

Many secret preparations of belt dressings, selling at a high price relative to the actual value of their ingredients, are on the market. In the main these consist of (1) mixtures of fats, waxes, tallow or degreas with castor or other fatty oils; (2) vulcanized corn or cottonseed oil thinned with a solvent (gasoline or benzol); (3) preparations containing wood tar, and (4) preparations containing pine rosin, which should never be used, as gums cause the leather fibers to mat together and become brittle. Too frequent application of oils softens the leather and makes it flabby and stretchy. Of the natural occurring materials, beeswax melted in castor oil is the preparation par excellence, not having any tendency to gum up or rot the leather. About one ounce of naphthol or phenol to the gallon of this dressing will aid materially in preventing mildew from injuring belting in damp localities.

Where a good and less expensive dressing is desired, properly prepared vulcanized corn or cottonseed oil proves worth the time of getting the chemicals and making up. The production of a soft, spongy, rubber-like substance by adding from 18 to 25 per cent of sulphur chloride to rape oil was started on a commercial scale by Parkes in 1855 (British patent, Oct. 22, No. 2399). Leather oils based on this sulphur-oil product were first developed in America about the year 1889 by A. Sommer of the Viscol Company. If 17 per cent of sulphur chloride is added to corn, rape or cottonseed oil, the oil will rise about 70 deg. C. in temperature after about ten minutes of reaction and a very viscous, almost solid, gel will be produced.

In producing large quantities of this vulcanized oil, overheating is prevented by adding the sulphur chloride in parts at intervals, thus allowing the mixture more time to cool. After the reaction is complete, the product is treated with sodium carbonate, together with a small amount of a mixture of alcohol and benzol (50-50). All free acids are immediately neutralized by the alkali, but as there tends to be a slight splitting off of acid for a considerable period, a small amount of good tallow soap dissolved in alcohol should be added to introduce a permanent neutralizer. The viscous vulcanized oil is thinned with any solvent such as gasoline, benzol, carbon tetrachloride, etc., to give a dressing of the desired penetrating power.

In perfecting skill in vulcanizing oils, it is better for the uninitiated to work with small amounts of material until good results are a certainty. A dressing having sufficient softening properties, very good pulley grip and but slight tendency to be drawn out by dust, so that it is quite permanent, can easily be made in the plant laboratory by this method.

# The Cottrell Processes in the Sulphuric Acid Industry

## Description of Installations for the Removal of Dust from Roaster Gases and Acid Mist from Exit Gases—Successful Installations for Treatment at High Temperatures

BY A. A. HEIMROD AND H. D. EGBERT

THE Cottrell processes of electrical precipitation are today fully established in the metallurgical field as a standard means of removing from gases finely divided suspended particles of dust and fume, and as such they will be found in use in many of the largest smelters and refineries throughout the country.

But while this field of usefulness is well recognized it is not so widely known that these same processes are also today beginning to fill a long felt want in sulphuric acid manufacturing plants and seem destined to come into more and more general use in this important industry. It seems quite fitting indeed that this should be the case for it was while engaged in research work on sulphuric acid manufacture that Dr. Cottrell carried out the experiments in electrical precipitation which became the foundation of the processes which today bear his name. In fact it was a mist or fog of sulphuric acid particles which he first precipitated by means of a high potential unidirectional current, and it was for the precipitation of sulphuric acid mist that the first commercial electrical precipitation plant was installed.

### APPLICATION IN MANUFACTURE OF SULPHURIC ACID

The Cottrell processes are today being used in sulphuric acid manufacturing plants for two different purposes: First, for cleaning the hot sulphur-dioxide-bearing gases after they leave the furnaces burning iron pyrites, zinc sulphide ores or other similar materials; and second, for removing and collecting the mist of acid carried by the exit gases coming from sulphuric acid concentrators or from the absorption towers in plants manufacturing the acid by a contact process.

It is the intent of this article to describe typical Cottrell installations designed by the Research Corporation for each of the above mentioned purposes, and in so doing it will be assumed that the majority of its readers need no explanation of the fundamental principles underlying the electrical precipitation processes. Those who may not be familiar with these principles or the terminology involved are referred to the literature on the subject<sup>1</sup> in which will be found a full discussion of the elements of electrical precipitation.

The problem of satisfactorily cleaning the sulphur dioxide gases prior to their oxidation and conversion into sulphuric acid has long been a troublesome one for acid makers to solve. In contact-acid plants it is of

course essential that the gases be completely freed from suspended particles of dust or fume prior to their passage through the catalyst and it is almost equally desirable in the case of chamber plants that the sulphur dioxide gases be thoroughly cleaned if the plant is to operate at high efficiency and produce a clear acid of good quality. In the latter case, however, the problem is complicated by the fact that the sulphur dioxide gases must be cleaned at a very high temperature whereas in contact plants the gases can be cooled during the cleaning process or can be cooled first and then purified.

### SOURCES OF DUST WHICH MUST BE REMOVED

Aside from crude sulphur or brimstone, pyrites, pyrrhotite and zinc sulphide ores are the materials most widely used as the source of sulphur dioxide gases which are later by oxidation converted into sulphuric acid. The roasting of these materials, especially when they are in a finely divided form, gives rise to much dust which must be removed from the gases before their passage through the further stages in the process of acid manufacture.

It is common practice in most acid plants to use furnaces of the type in which the charge is continually agitated while being roasted, and this materially tends to increase the amount of dust carried over by the gases produced by such furnaces, thus making still more important the installation of some means of cleaning the gases. Of course when brimstone is burned the dust problem is eliminated since the gases coming from the burners are practically free from suspended particles of dust or fume.

War conditions have so interfered with the importation of pyrites that many plants are today burning sulphur which under normal conditions would use pyrites and they are thus for the present free from dust troubles. This is only a temporary situation however, and with the resumption of pyrites importation the cleaning of the gases as they come from the roasting furnaces will once again be a necessity. Plants now burning brimstone must therefore look to the future and they should take steps now to provide suitable means for cleaning their furnace gases, as will be necessary when pyrites are again available. Designers of new plants should leave ample space for the installation of suitable gas-cleaning system even though there is no present need for such apparatus because of the use of brimstone instead of other forms of sulphur-bearing materials.

In designing Cottrell precipitators for cleaning roaster-furnace gases the temperature at which the gases must be cleaned and the character of the suspended matter to be removed from such gases are gov-

<sup>1</sup>Problems in Smoke, Fume and Dust Abatement. By F. G. Cottrell. From the Smithsonian Report for 1913. Solution of Smoke, Fume and Dust Problems by Electrical Precipitation, by Linn Bradley. *Metalurgical & Chemical Engineering*, Vol. XIII, No. 15, December 1, 1915. Recent Progress in Electrical Smoke Precipitation. By F. G. Cottrell. Presented before the Second Pan-American Scientific Congress, Washington, U. S. A., December 27, 1915-Jan. 8, 1916.

#### TYPICAL INSTALLATIONS OF COTTRELL PRECIPITATORS

FIG. 1—Cleaning gases from zinc roasters. FIG. 2—Cleaning gases from sulphuric acid concentrators. FIG. 3—Removing sulphuric acid mist from exit gases; current on. FIG. 4—Same; current off. FIG. 5—Removing acid mist. FIG. 6—Interior view of equipment to clean hot roaster gases.

erning factors. Of course the size of the installation depends directly upon the volume of gas to be cleaned and this in turn is fixed by the quantity of material being roasted per unit of time and by its sulphur content as well as by the percentage of sulphur dioxide in the gases leaving the furnaces. These factors must therefore be known or approximated in order that a precipitation plant of suitable capacity may be provided. Two types of precipitators are today being installed for cleaning the hot furnace gases in sulphuric acid plants. These types differ widely from each other and the decision as to which type should be installed is based largely upon the temperature and fume or dust conditions to be met in the particular plant under consideration. In cases where the gases must be cleaned

shortly be used for the manufacture of sulphuric acid by the contact method.

#### CLEANING ZINC ROASTER GASES

With three kilns in operation the volume of gas passing through the precipitator at the above-mentioned temperature is 17,500 cubic feet per minute and there will be collected under such conditions about 7600 pounds of material per twenty-four hours having the following analysis: Zn 22 per cent, Fe 30, Pb 2.2, S 30.

The precipitator as installed consists of two units each having 36 collecting electrode tubes or pipes. These pipes are of steel, 12 in. in diameter and 15 ft. in height. The discharge electrodes are No. 10 jack chains suspended in the vertical axis of each pipe. Means are provided for rapping both the discharge and collecting electrodes in order to remove from time to time any dust which may have adhered to them. The levers for operating the pipe rappers may be clearly seen in the photograph. The bottom header is a reinforced concrete chamber into which the collecting electrode pipes project and in which the collected material is deposited. This is later removed by hand through doors which are provided for this purpose. Should it be desirable, similar installations could be readily provided with hoppers and screw conveyors so that the collected dust could be taken out of the precipitator continuously and automatically. This precipitator occupies a space approximately 17 ft. wide by 28 ft. long and

has an overall height of about 35 feet. The electrical equipment provided for furnishing the high-potential unidirectional current required by the precipitator consists of a 200 to 65,707 50 85,000-volt transformer operated directly from the plant power line, a mechanical rectifier driven by a 3-hp., 3-phase, 60-cycle synchronous motor also operated directly from the plant power line and a switchboard panel with the necessary instruments and control

apparatus such as circuit breaker, rheostats etc. The amount of power required to operate the installation is about 18 kw.

#### OPERATING AT A TEMPERATURE OF 1100 DEG. F.

Fig. 7 is a drawing giving the general arrangement and overall dimensions of a precipitator of the horizontal-flow or plate type, designed and installed by the Research Corporation, and Fig. 6 is a photograph taken looking in a lengthwise direction through a precipitator of this kind which was installed in a chamber acid plant near Baltimore, Maryland, and which is particularly designed to withstand the high temperatures at which the gases must be cleaned in such a plant. This installation operates at a gas temperature of 1100 deg. F., while occasionally temperatures as high as 1400 deg. F. have been recorded in the precipitator.

A precipitator of the size shown in Fig. 7 will clean the hot gases produced by the roasting of 40 to 45 tons of fine pyrites per twenty-four hours. With a sulphur dioxide concentration of  $7\frac{1}{2}$  per cent to 8 per

FIG. 7.—GENERAL ARRANGEMENT FOR CLEANING ROASTER GASES

at temperatures of 1000 deg. F. and over, and where the suspended matter to be removed is mostly dust rather than fume, precipitators of the so-called "plate type" in which the gases pass horizontally between the collecting and discharge electrodes have proved highly satisfactory. On the other hand where the gases can be cooled before cleaning to a temperature of about 600 deg. F. or under and where the suspended matter to be removed is fume rather than dust, precipitators of the pipe type in which the gases pass vertically upwards between the collecting and discharge electrodes would in general be the most suitable.

Fig. 1 is a photograph of a Cottrell precipitator of the last mentioned type which was recently installed under the supervision of the Research Corporation at a plant in Wisconsin. Here the gases to be cleaned come from three Mathey rotary kilns, each roasting a little over two tons per hour of Wisconsin zinc ore concentrates having the following approximate analysis: Zn 30 per cent, Fe 30, Pb 0.75, S 35. The gases are cleaned at a temperature of about 500 deg. F. and will

cent this means that the volume of gas passing through the installation is about 17,500 cubic feet per minute at a temperature of 1100 deg. F.

The installation at Baltimore just referred to takes the gases from two 22-ft. diameter, 7-hearth Herreshoff furnaces, each of which burns from 20 to 25 tons of fine iron pyrites per 24 hours. Between 900 pounds and 1200 pounds of dust which is practically all  $\text{Fe}_2\text{O}_3$  is collected per day by the precipitator. The iron content of the acid made with the Cottrell plant in operation is only 0.044 per cent.

As will be noted from an inspection of Fig. 7, the precipitation installation is divided into two sections each of which is provided with a damper at both inlet and outlet ends. This makes it possible to shut off either section from the system when inspection or repair is required or when it is desired to clean the electrodes as may be necessary every few days if a very dusty ore is being roasted in the furnaces. For the above reason it is desirable to so design the plant that each section will have sufficient capacity to handle all the gas for short periods of time and in this way, barring unusual accidents, continuity of operation with clean gas is practically assured.

It has been found by experience that cast-iron jug dampers give the most satisfactory service under the severe temperature conditions which are met with in installations of this character, and room for the installation of dampers of this type should be provided wherever possible.

#### DESIGN OF ELECTRODES FOR HIGH TEMPERATURE WORK

The collecting electrodes of precipitators such as are shown in Figs. 6 and 7 are heavy steel plates reinforced with angle iron stiffeners and suspended in parallel rows in a brick-walled chamber. The discharge electrodes are heavy steel strips or angle irons suspended midway in each of the spaces between the parallel collecting electrode plates.

The discharge electrodes are held in place by frames which are rigidly braced and fastened together at the ends. The frames are suspended from longitudinal T-shaped cast-iron members which in turn rest on transverse beams also made of cast iron but of rectangular shape and cast hollow. These transverse beams are themselves suspended by means of cold-rolled steel rods passing through the roof of the precipitator and supported by a framework carried on insulators placed above and outside of the precipitator. This type of construction is especially advantageous where high gas temperatures exist because the insulators which support the weight of the discharge electrode system are entirely out of the precipitator and thus are removed from all contact with the hot gases. They are therefore subject to no unusual strains and can be easily inspected and cleaned whenever necessary. Insulation must, of course, be provided at the points where the steel supporting rods pass through the roof of the precipitator. This is accomplished by the use of pyrex glass bowls or by oil lutes. In the latter case the oil which is the insulating medium also acts as a seal to prevent the leakage of air at these points.

It is usual to design installations of this type to operate at relatively low voltages in order to simplify the

insulation problem and for this reason a working voltage of only about 50,000 volts is used in actual practice.

The walls of the precipitator are of brick laid up in three courses in which fire brick, insulating brick and ordinary brick are used respectively. Outside of this is placed a steel casing which serves both to strengthen the walls and to prevent the leakage of air. The entire precipitator structure is supported on heavy steel columns and is elevated to a sufficient height above the ground so as to allow for hoppers into which the dust falls as it is removed from the gases. The hoppers terminate in screw conveyors which serve to carry the collected material away from beneath the precipitator.

#### SMALL POWER CONSUMPTION

The power consumption of installations of the above character operating on gases from furnaces roasting iron pyrites is usually quite small. This is the case with the precipitator at the acid plant near Baltimore which has just been described and where the power used is not over 2 kw. The electrical equipment provided at this plant consists of a 200 to 30/35/40/45/50,000-volt transformer operated directly from the plant power line, a mechanical rectifier driven by a 2-hp. 750-r.p.m. 3-phase, 25-cycle synchronous motor also operated from the plant power line and a switchboard panel with the usual control apparatus, instruments etc.

During the concentration of sulphuric acid a certain amount of acid mist is always formed which passes out from the concentrating system with the exit gases. The amount of mist thus carried off depends to a large extent upon the degree to which the concentrator is being forced as well as upon the type of concentrator in use. The mist, however, is almost always present in sufficient quantity to constitute a neighborhood nuisance even if the actual loss of acid is not a serious matter, and some means must be provided to remove it from the concentrator gases before they are discharged into the air. The installation of coke towers and similar scrubbing devices will remove only a portion of the mist and it is therefore not surprising to find that a large number of Cottrell precipitators have been installed and are today satisfactorily solving the acid mist problem in many sulphuric acid concentrating plants.

#### REMOVAL OF MIST FROM EXIT GASES

Precipitators installed for this service are of the pipe type and must of course be constructed of acid-proof materials. Lead is almost always used for the top and bottom headers, while the collecting electrode pipes are of lead or tile as may be found convenient. Figs. 2 and 5 are photographs of two Cottrell precipitators which have been recently installed under Research Corporation supervision to remove the acid mist from the gases coming from sulphuric acid concentrators. Fig. 3 shows the effect of the high potential current on the cloud of acid mist which issues from a precipitator of this type when the current is off as seen in Fig. 4.

The precipitator shown in Fig. 2 treats the gases given off by three concentrators of the tower type producing together a total of about fifty tons of 66° Bé. acid per twenty-four hours. About 3000 cubic feet of gas per minute at a temperature of 135 deg. F. passes through the precipitator and from this is collected about

3000 pounds per twenty-four hours of 18° Bé. acid. The draft necessary for the proper operation of the concentrators is provided by a fan placed between the concentrators and the precipitator and also to a certain extent by a stack to which the gases pass after leaving the precipitator.

One Cottrell unit is provided which has 16 collecting electrode pipes built of sectional tile with joints set up in acid proof cement. All of the pipes are 15 ft. in height and all are 12 in. in diameter with the exception of two of the corner pipes which have a diameter of 16 in. These are made larger to provide for the larger

FIG. 8.—TYPICAL INSTALLATION OF ELECTRICAL APPARATUS

and rigid discharge electrodes which are placed in the corner pipes and which serve to hold steady the entire discharge electrode system. The discharge electrode in each of the other fourteen pipes is an iron wire enclosed in a thick star-shaped lead casing. The top and bottom headers of the precipitator are of lead and with the pipes are supported on a timber framework.

Dampers of the jug type are provided and are so arranged that the gases from any one or all of the three concentrators can be shut off from the precipitator at will. Furthermore provision is made so that all the gases can be by-passed around the precipitator to the stack should it be necessary to shut down the installation for the purposes of repair etc.

#### INSULATORS MUST HAVE LARGE SAFETY FACTOR

In Cottrell installations for the collection of acid mist great care should be taken with the insulators supporting the high potential parts of the precipitator. Insulators with a large safety factor as regards voltage rating must be provided and they must be well protected from the acid fumes. In practice it has been found best to depend on the stiffness of the lead covered discharge electrodes to prevent them from vibrating and to provide no insulators in the bottom header of the precipitator. The insulators now generally used in the top header to support the discharge electrode framework are of the corrugated post type made of one piece of porcelain and covered with hoods to protect them as much as possible from the deposition of acid or moisture.

The electrical equipment provided for the installation just described consists of a 5-kva. 200 to 65/70/75/80/85,000-volt transformer operated directly from the plant power line, a mechanical rectifier driven by a 3-hp. 1800-r.p.m. 60-cycle synchronous motor and a switch-

board panel with the necessary control apparatus. The precipitator operates at a potential of 75,000 volts and the power consumption of the installation is about 3½ kilowatts.

The precipitator shown in Fig. 5 cleans 2500 cubic feet of gas per minute at a temperature of 200 deg. F., coming from two concentrators of the tower type producing a total of forty tons of 66° Bé. acid per twenty-four hours. This installation collects approximately 3500 pounds per twenty-four hours of acid having a concentration of 33° Bé.

There is one precipitator unit supported on a timber framework and having twelve collecting electrode pipes each 12 in. in diameter and 15 ft. in height. The pipes in this case are of lead as is also the bottom header. The top header is of frame construction lined with lead. Lead covered iron wire is used for the discharge electrodes. The electrical equipment is of the type previously described and is housed in a small frame building placed close to the precipitator.

#### CLEANING 30,000 CUBIC FEET OF GAS PER MINUTE

One of the largest precipitation installations now in service for the removal of acid mist arising from sulphuric acid concentrators is that which was recently installed to clean the waste gases from twenty-two concentrators of the cascade type, each having a rated output of ten tons of 66° Bé. acid per twenty-four hours. The volume of gas cleaned averages thirty thousand cubic feet per minute at 180 deg. F. and there is collected some twenty-five tons of 40° Bé. sulphuric acid per day. The precipitator consists of four units, each having twelve collecting electrode pipes 12 in. in diameter by 15 ft. in height. The precipitators are constructed of lead throughout and are supported on a timber framework. One set of electrical equipment of the usual type furnishes the power acquired by the installation, switches being provided in the high voltage line so that any precipitator section can be disconnected at will. In the case of each of the installations which have just been described fans placed between the precipitator and the concentrator are used to create the necessary draft.

#### STEAM JETS USED TO INDUCE DRAFT

In some instances steam jets have been used for this purpose but these are not as satisfactory and the acid reclaimed by the precipitator is in such case of a much lower concentration due to the condensed moisture from the steam jet which is precipitated with the acid mist. That portion of the steam which is not condensed prior to passage through the precipitator is, of course, not removed from the gas but passes out and condenses on being discharged into the cooler air. Thus the usual clearance obtained by a precipitator treating the gases from a concentration system in which steam jets are used as a source of draft is not complete, due to the cloud of condensed steam produced at the precipitator exits. The acid mist, of course, is completely removed in either case.

In plants manufacturing sulphuric acid by the contact process there is often a considerable amount of acid mist escaping from the absorption towers, especially when the plant operating conditions are abnormal. When the plant is located near a residential

or in a highly cultivated agricultural district the mist escaping at such times may be a cause of considerable nuisance or damage to surrounding property owners. In such cases also the Cottrell processes have been successfully applied for the removal and collection of the acid mist from the exit gases.

There are still other points in the process of sulphuric acid manufacture where the Cottrell processes of electrical precipitation might be applied with interesting results leading to additional economies and improvements in operation, and experiments are about to be conducted by the Research Corporation looking toward further development along these lines in the near future. The cleaning of the roaster gases and the removal of acid mist from concentrator and absorption tower exit gases is, however, an established commercial use of the Cottrell processes and one in which they are coming more and more into universal use.

Research Corporation, New York City.

### Conservation of Technical Engineers

**T**ECHNICAL engineers of every branch of the profession who are taking part in the war activities of the Army and Navy are alarmed at the unfortunate waste of technical training caused by the drafting and enlisting of engineers for regular service with little or no regard for their technical attainments. These technically educated and experienced men are essential to the successful conduct of the war and cannot be replaced. There is continuing evidence that America is repeating in some measure England's mistake of sending technical men into the ranks when they should be carefully conserved for special duties in the fighting forces or on the technical staffs of the Army, the Navy and the essential war industries.

These facts have been forced upon the attention of engineers who have been co-operating with the Government through the Naval Consulting Board, the National Research Council and Engineering Council. Upon these organizations requests have constantly been made for engineers, chemists and other technical men for a great variety of military services. Thousands of names have thus been furnished to the Government departments and bureaus. Engineering Council especially has devoted attention to this personnel work through its committee, known as American Engineering Service, which has available classified lists of approximately 25,000 engineers, and besides unclassified lists of many more. It is from these lists, directly or indirectly, that most of the names have been selected for war service.

Engineering Council was founded by the American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers and American Institute of Electrical Engineers; and other engineering societies are co-operating with it in this service, the total membership represented by these organizations being approximately fifty thousand. Already from 10 to 15 per cent of the members of these several organizations are in the uniformed services of the country and it is safe to say that a large majority of their remaining members are in the Government civilian service or otherwise directly or indirectly engaged in the War. Engineers do not seek

to avoid fighting, but earnestly desire to be given opportunities for fighting and other services in which they can be most effective and which cannot be performed by others.

It is known that through the Committee on Classification of Personnel in the War Service Exchange (of the War Department) and some other ways, efforts are being made to counteract the tendencies toward the loss of our technical men in the ranks of the Army and Navy. It is believed, however, that these efforts are insufficient and that they should at once be supplemented by other stringent measures dealing with the subject in the Draft Boards and recruiting stations.

In view of the foregoing, Engineering Council, created to provide means for united action and to speak authoritatively for its member societies on all public questions of common interest to engineers, respectfully offers the following:

WHEREAS, technically trained engineers are indispensable to the Army, the Navy and the war industries, in engineering corps, ordnance bureaus and signal corps, in aviation, submarine and tank service, in shipbuilding, and in many other assignments; and

WHEREAS, through draft and otherwise many of these irreplaceable men have been and are being diverted so that their special qualifications are not being utilized, be it

*Resolved*, that in the opinion of Engineering Council technically trained men of all ages should be enrolled and conserved for technical duties, and special efforts should be made immediately by the War and Navy Departments to find and record such men among drafted and enlisted forces and to assign them to places in which their special qualifications are needed, and be it further

*Resolved*, that Engineering Council offers to assist the War and Navy Departments in locating and classifying such men, if its assistance be desired, provided these departments will give the necessary facilities for collecting information about engineers now in the Army and Navy, or whose names are upon the selective draft lists.

These resolutions are offered solely in a patriotic spirit of helpfulness. They are published here with the assurance to the Secretaries of War and the Navy that the resolutions have our hearty approval and are worthy of favorable consideration.

### Japanese Coke Production

The statistics on metallurgical coke for the past year are published by *The Chemical Technology* of Tokio as follows:

|                             | Tons    |
|-----------------------------|---------|
| Government Iron Works.....  | 365,000 |
| Mitsui's Miike .....        | 100,000 |
| Tokio .....                 | 80,000  |
| Osaka .....                 | 48,000  |
| Makiyama .....              | 40,000  |

# The Metallography and Heat Treatment of Metals Used in Aëroplane Construction—IV

## Uses of Copper and Its Alloys in Aeroplane Construction—Requirements for Sheets and Tubes—Details of the Brazing Process, Methods of Heating, Fluxes and Preparation of Parts

By F. GROTTTS

Chief Metallurgist, Curtiss Aëroplane and Motor Corporation.

### COPPER

**C**OPPER is used as tubing for gas lines and in sheets for tanks and propeller tips. The average chemical analysis is about 99.80 per cent Cu.

Copper sheet should be free from buckles, seams, discolorations and capable of being bent flat without cracking. In order to meet the bend test annealing is sometimes necessary. Annealing consists in heating the copper to such a temperature as will give the required softness and then quenching in water. In most cases 1000 to 1100 deg. Fahr. have been satisfactory temperatures for annealing.

#### PHYSICAL PROPERTIES RAW STOCK

|      | Tensile Strength, Lb. | Elongation, % |
|------|-----------------------|---------------|
| Soft | 30,000                | 25            |
| Hard | 35,000                | 18            |

In the following experiments on annealing it is noticeable that the ultimate tensile strength remains nearly constant while the yield varies inversely with the increase of temperature:

| Temp. | Time, Min. | Quenched, or Cooled | Tensile Strength, Lb. | Yield Point, Lb. | Elongation, 1 in Cent |
|-------|------------|---------------------|-----------------------|------------------|-----------------------|
| 600   | 30         | H <sub>2</sub> O    | 31,200                | 14,740           | 40.5                  |
| 600   | 30         | Air                 | 30,000                | 13,500           | 43.0                  |
| 800   | 30         | H <sub>2</sub> O    | 30,900                | 12,080           | 47.0                  |
| 800   | 30         | Air                 | 32,150                | 12,700           | 45.3                  |
| 1,000 | 30         | H <sub>2</sub> O    | 31,200                | 11,740           | 46.2                  |
| 1,000 | 30         | Air                 | 31,000                | 10,800           | 46.8                  |
| 1,200 | 30         | H <sub>2</sub> O    | 31,450                | 9,900            | 48.0                  |
| 1,200 | 30         | Air                 | 31,700                | 10,000           | 47.0                  |

#### FAILURES DUE TO FAULTY WORKMANSHIP

Several cases of copper sheet failing have been found. They were noticed because of gasoline leaking out. Examination showed fine cracks extending out from the soldered joints, as shown in Fig. 89. These fine cracks were due to faulty workmanship, and the vibration from the motor caused the copper to give way.

By faulty workmanship is meant cases where the solder is allowed to flow out in jagged points from the joint. It creates a stiffness which will localize any vibration. Ofttimes the tanks are so designed as to cause certain parts to be subject to unnecessary stress. Copper under stress will soon fail when subjected to excessive vibration. It was thought by some to be necessary always to solder copper joints with soft solder or silver solder, but brazing material works very nicely, especially for tubing.

Joints between copper and brass can be made with brazing material, but solder or silver solder is safer, minimizing danger of burning the brass.

Sheet copper on propeller tips often fails because of mashing or straining in tacking on. Dents from hammers start cracks, and because of the speed of the pro-

peller these open up. Many cases have been reported as crystallization in the copper from the rapid motion, but to date such a failure has not been found here. Such examples have been found to start from either excessive or careless hammering, or straining the copper sheet in place.

The use of the blow torch on copper tanks should be discouraged because of danger of gassed copper, illustrated in Fig. 90.

The reducing element, hydrogen, of the torch combining with oxygen forms water. This water which is immediately converted into steam forms hair cracks which grow rapidly when stressed or vibrated.

#### TESTS FOR COPPER TUBING

Copper tubing for gas lines, etc., as made from cast ingots: This is hot-pierced and rolled, then finished by cold-drawing to the desired strength. This material is given three tests:

**Flattening test**—A section of tubing two inches long is flattened with a hammer until it will pass through a micrometer set to three times the thickness of the tube wall; no cracks should appear.

**Crush test**—A section one and one-half inches long must be crushed endwise to half its original length without cracking.

**Bend test**—Tubing as it is must be bent at an angle of 180° with a radius of half the thickness of the wall. Annealed specimens taken from the tubing should not crack when hammered to a fine edge. Joints in this materials were for a time only made from silver solder, as there were many cases of burned tubing. Brazing material makes a good joint and is much cheaper. The temperature necessary for successful brazing is not high enough to spoil any tubing. As copper tubing is bent into many shapes it is necessary to anneal it. The following tests were made on copper tubing of an analysis of 99.87% Cu.

| Temp.     | Time, Min. | Quenched         | Ultimate Strength, Lb. | Yield Point, Lb. |
|-----------|------------|------------------|------------------------|------------------|
| 400       | 30         | H <sub>2</sub> O | 35,700                 | 15,350           |
| 600       | 30         | H <sub>2</sub> O | 35,250                 | 13,430           |
| 800       | 30         | H <sub>2</sub> O | 35,600                 | 12,980           |
| 1,000     | 30         | H <sub>2</sub> O | 35,200                 | 9,130            |
| 1,200     | 30         | H <sub>2</sub> O | 33,400                 | 8,940            |

#### BRASSES AND BRONZES

Brasses and bronzes give lots of troubles, as the material oftentimes is internally stressed by cold drawing to get a high tensile strength. These stresses are not shown by chemical analysis, physical tests nor microscopic examination. Machining, temperature variations,

FIGS. 89-96

Fig. 89—Fine crack in copper sheet, extending from soldered joint. Fig. 90—Gassed copper resulting from use of blow torch. Fig. 91—Tobin bronze before treatment with mercurous nitrate. Fig. 92—Tobin bronze after treatment with mercurous nitrate. Fig. 93—Manganese bronze. Fig. 94—Film of oxide in brass bar. Figs. 95 and 96—Cracks resulting from over-heating

corrosive agents, vibration, will cause the strains to become cracks. These cracks are sometimes called season cracks. They are peculiar to brasses and bronzes of less than 80 per cent copper. This type of alloy has a greater percentage of the brittle copper-zinc constituent than where the material runs over 80 per cent copper.

Annealing helps to remove these stresses and increases the elongation. The average temperature in annealing is about 700 deg. and the quenching is done in water. Water-quenched material seems to give more even results than air-cooled.

TOBIN BRONZE

Tobin bronze used for turnbuckles has an average analysis of 60.24 Cu, 0.67 Sn and 38.59 Zn. In order to remove stresses and meet specifications it is annealed at

different temperatures.

Extensive investigations have proved that turnbuckle barrels when made from stressed bronze will crack when exposed to corroding agents such as ammonium hydroxide and sodium chloride. These failures nearly always trace their origin to trying to get a high tensile strength from drawing. This places the material in a strained condition and the cracks will appear during machining

or when subject to corrosion. It is interesting also that a turnbuckle barrel will sometimes pass inspection and then it will show up with large cracks seemingly from no cause whatever. In order to detect these internal strains a section about two inches long is taken from each rod, cleaned and polished and then immersed in a solution of mercurous nitrate (65 g.  $\text{HgNO}_2$ —15 cc.  $\text{HNO}_3$ —900 cc.  $\text{H}_2\text{O}$ ) for twenty minutes. At the end of that time they are cleaned off and examined. The failure from the stressing will appear at once. The photographs reproduced in Figs. 91 and 92 show the material before and after being in the mercury solution.

Impurities often found are As, Sb, Bi, Fe and Pb. Arsenic is not so detrimental as Sb or Bi, which makes the material brittle, due to the fact that they will not form a solution but form thin layers between the crystals. A small quantity of iron (0.09) is not detrimental. Lead occurs in the Zn as minute globules.

#### MANGANESE BRONZE

Castings are made from lake or electrolytic copper and spelter. This spelter has an analysis of

Pb 0.15, Fe 0.03, Cd 0.15, and Zn remainder.

The castings should be free from blow holes and spongy spots.

The average physical properties are tensile strength, 70,000 lb.; yield point, 30,000 lb.; elongation, 15 per cent. Chemical analysis, 59% Cu, 40 Zn, 0.15 Pb, and 3.0 Sn, Fe, Mn, and Al.

Several cracked sections were found that were caused from the welding in of a part. The strains produced by such an operation can be relieved by subsequent annealing.

#### GUN METAL

Gun metal is made from lake or electrolytic copper (99.88) and pig tin (99.0). It is used for instruments and finishings. It has an average chemical analysis of 87.5% Cu, 10.0 Sn, 2.0 Zn, 0.2 Pb and 0.15 Fe.

Physical properties: ultimate tensile strength, 30,000 lb.; yield point, 15,000 lb.; elongation, 15 per cent.

#### MONEL METAL

Monel metal is used for sheathing of aeroplane propellers. It is cold-rolled and should be clean and of uniform color. It is subject to a bend test, that is, hammered double without cracking. It has been remarkable because of the small number of flaws and defects found.

The average chemical analysis is:

Cu 25%, Ni 66, Fe 3.5, Mn 3.5, Impurities 1.0.

Physical properties: Ultimate tensile strength, 70,000 lb.; yielded point, 35,000 lb.; elongation, 25 per cent.

#### BRASS

Bearings, bolts, nuts and brazing wire are made from brass. Bearings are made from yellow brass which has an analysis of Cu 64.5, Zn 34.8, Pb 3.2, impurities 0.37

Defects found are principally in the form of spongy spots and inclusions.

Bar brass for nuts and bolts in the raw state has the following physical properties: Tensile strength, 65,009 lb.; yield point, 42,500 lb.; elongation, 22 per cent; reduction, 48 per cent.

Chemical analysis: Cu 60.1, Sn 0.45, Fe 0.08, Pb 0.22, Zn remainder.

One bar was rejected because of a thin film of oxide shown in Fig. 94. This flaw showed up when machining and was probably due to carelessness in casting. Oxide was not all removed and afterward showed up in the bar.

#### FLUXES FOR BRAZING BRASS

Joints are made in tubing and sheet-steel by brazing. The parts to be joined should be carefully cleaned in order that the brazing material may have a good surface to adhere to. Fluxes such as borax are used to do away with any oxides formed.

The sheet or tubing should not be sandblasted before brazing as the material will not flow readily and overheating of both steel and bronze sometimes results.

There are two brazing materials used, one having an analysis of 80% Cu, 0.3 Pb, 0.1 Fe, 1.25 impurities, Zn remainder; and the other having about 58 to 60% Cu and 40 to 42 Zn.

The first is preferable as the steel can be heat-treated afterward without damage to the braze.

Ammonium chloride, zinc chloride and sodium chloride (salt water) will sometimes give a reddish brown appearance to the braze. This indicates a slight dezincification, which means the braze is spongy and weak. Failure has been known to result from such joints.

#### CONSIDERATION OF THE BRAZING PROCESS

Brazing is a method of joining the parts of higher-fusing metals, usually steel or copper, by the use of a lower-fusing copper-zinc alloy, usually called "spelter," or in the case of steel or iron parts, of copper alone.

The parts to be joined are heated a little above the fusing point of the metal used to make the union, a substance applied, called a flux, which will fuse and dissolve all the metallic oxides present, and the brazing metal applied in such a manner that it will melt and flow into the spaces where the union of parts is desired. The parts are then allowed to cool in air, after which the joint is finished by removing the adhering flux and the superfluous brazing metal.

Brazing is sometimes referred to as "hard soldering," in distinction from "soft soldering," in which the uniting metal is a tin-lead alloy.

When a silver alloy is used as the uniting metal the process is called "silver soldering."

There is no single term which includes all of these methods.

In the brazing process the following items should be considered:

Composition and character of the brazing metal

Methods of heating parts

Composition of the flux

Preparation of the parts for the process

Cleaving the joint after being made

Effect of the process upon the metal of the parts joined.

*Brazing metal*—The "spelter" commonly sold in the trade is a "low brass," i.e., a brass having a comparatively low copper content, the object apparently being to keep the melting point as low as possible. The copper content should never be less than 55 per cent, as any further reduction very rapidly weakens the alloy.

The ultimate strength of a brazed joint clearly depends upon the strength of the brazing metal forming the union. Other things being equal, therefore, the metal

having the greatest strength should be used; but there are several conditions which affect the choice. This is the attraction which causes a liquid to "wet" a solid. In the case of brazing the attraction of the molten spelter for the iron, or other metal of the joint, exceeds that of the flux, so that it attaches itself to the other metal. There must also be no physical obstruction to this wetting action.

It is probable that there is a superficial alloying of one or both metals in the spelter with the iron, which forms the actual union, since the adhesion of the spelter to the iron is always stronger than either the iron or the spelter. In testing butt brazes of mild-steel rods either the brass or the steel parted; the brass never separated from the steel.

The "flow" of the spelter depends upon the wetting attraction, and the absence of physical obstructions. The chief physical obstruction is metallic oxide which forms on the surfaces of the heated metals, especially upon the surface of the molten brazing metal. Unless the oxides formed are instantly dissolved in the flux they form a film on the surface which prevents the union of the metals. It is highly important, therefore, that the brazing metal contain no metal whose oxide is insoluble in the flux used.

**Fluxes.**—The most satisfactory fluxes for brazing with copper-zinc alloy are borax, and boric or boracic acid. The latter is preferable because it contains no water of crystallization and melts down without frothing. Borax contains a large amount of water of crystallization, which is driven off in the first heating, causing it to froth violently, which causes it to be blown off by the torch or blast flames.

Iron, copper, and zinc oxides are freely soluble in molten boric acid, forming their respective borates.

Tin and aluminium oxides do not form borates. The presence of these metals in brazing spelter must therefore be considered as deleterious impurities; they interfere with the flow, and if in any considerable quantity prevent it altogether.

Copper and brass have the peculiarity of dissolving their own oxides, and these will interfere with the flow of the metal. Brazing spelters should be clean metal, i.e., free from dissolved oxides, and impurities in suspension.

In practice a brass having a higher copper content than that usually given as having the greatest tensile strength was found to make the strongest joint. The best results were obtained with a brass having practically the composition specified by the Signal Corps, viz:

|                        | Per Cent  |
|------------------------|-----------|
| Copper .....           | 78 to 82  |
| Lead (maximum) .....   | 0.3       |
| Iron .....             | 0.1       |
| Total impurities ..... | 1.25      |
| Zinc .....             | Remainder |

Experiments indicate that the iron content can be considerably higher than the amount given above without harm, while the maximum of allowable impurities appears high. But brazes made by the acetylene torch with metal containing 83 per cent copper showed a greater tensile strength, in a number of cases, than the steel, the joint holding while the steel parted.

Brazing metal is changed in composition and, where the acetylene torch is used, may be changed in crystal-

line structure, by the process. In gas-fire brazing it loses about 2 per cent of zinc, and in acetylene brazing it may lose as much as 6 per cent. The difference in color cannot be due to the change in composition, since brass of the same composition is pure yellow; it is probably due to a difference in the nature of the solid solution forming the alloy, the pink tint arising from the presence of beta crystals. This theory would also account for the considerably greater strength of joints brazed by the acetylene torch. The difference in crystalline structure is clearly shown in the micrographs of the braze of acetylene and fire-brazed joints.

Pure copper is inferior to good brass as a brazing metal. It requires a considerably higher temperature, with increased labor and danger of burning the steel, does not flow as well, and the finished joint is weaker.

**Methods of Heating.**—The essential in making a good brazed joint is to have the parts of such a temperature that the brass flows freely, but not hot enough to "burn" the metal. This requires special care in the use of the acetylene flame in cases as light-gage tubing. Cases were found in which the tubing had been melted through and the hole covered with spelter. On the other hand, if the temperature falls too near the freezing point of the brass it forms a coarse, granular, brittle structure, thus weakening the joint. The intense heat of the acetylene flame tends to produce bubbles in the braze, probably by the rapid evaporation of zinc. This can be avoided, or reduced to a minimum, by taking a little more time and not trying to force the heating.

The acetylene flame produces the strongest joint, the gas-fire the next best, and dip-brazing the weakest. The weakness of the dip-braze is no doubt due to the fact that, as ordinarily practiced, the steel does not become any hotter, and possibly not as hot, as the molten brass. Dip-brazing should, therefore, be used only for joints in which there are large contact surfaces, such as reinforcements of tubing, and similar constructions. The average increase in strength of acetylene-brazed joints over fire-brazed in a series of experiments was 8.5 per cent.

**Preparation of Parts.**—Steel parts should be free from adhering foreign matter, and from scale; the ordinary film of oxide does not matter. Sand blast should never be used to clean joints before brazing. The rough surface produced greatly interferes with the flow of spelter; and in the effort to overcome this, the workman overheats the steel, with the result that cracks, both in the brass and the steel, develop on cooling. Figs. 95 and 96.

The supposition that sand adheres to the steel and prevents the flow of spelter is erroneous; microscopic examination of the surface showed it to be perfectly clean. The effect is entirely physical. Where the size of the parts would admit they could be very effectively cleaned by tumbling with sand or other suitable material, which would leave the surfaces smooth and polished. "Pickling" with acid is unsafe, as it is very difficult to so completely remove the last traces as to prevent subsequent corrosion.

Parts to be united are held together either by pinning, or "tacking" with welds made by the acetylene torch. Pinning is generally used in assembling parts with tubing. Pins should be cut flush and "set" by spot-welding

the ends with the acetylene torch. Except where they are very large it is difficult to rivet them as they buckle in the tube. If left without being set they are of no practical use after the joint is finished, whereas they would form a large factor of safety if welded. Where joints are assembled by tacking, care should be taken to make the welds as small as possible; if large welds are made the lumps of iron left interfere with the filing of the joints after brazing.

Joints formed by crushing parts together while red hot, as in forming eyes on the ends of tubing, contain so much scale that it is not dissolved out by the flux, and therefore the spelter does not flow into the spaces where union is desired. In such cases the joint should be dipped in spelter and crushed into shape by a die press while the spelter is still fluid. This would insure complete union of parts, and save one operation. Where fillets are to be made the piece must be held so that the natural flow of the spelter will make a fillet of equilateral section. If the piece is not so held the fillet will spread out on one side and draw away from the other, causing extra labor to fill up the joint, and leaving a poor job in the end. A vise having a universal adjustment should be used for holding pieces that are to have fillets put in.

**Cleaning Brazed Joints**—Cleaning a brazed joint involves removing the black iron oxide, or scale, the fused borax, and the excess spelter. Sand blast affords a perfectly satisfactory method of removing scale and flux, except where brazing must be done afterward. For removing excess spelter a small electric or pneumatic hammer, fitted with suitable chisels, would do quicker and better work than filing. Power emery belts, properly arranged, can do most of the work of polishing after the excess spelter has been removed. Where sand-blasting is not feasible the borax can be removed with hot solution of carbonate of soda, which has no bad effect upon either the brass or steel.

**Effect of the Brazing Process on Steel**—The temperature required to melt brass is sufficient to anneal the steel to which it is applied. If the steel has been "tempered" by cold-working such as rolling or drawing, the effect is to increase ductility and reduce tensile strength.

### Coke Prices Reduced

Reciting the fact that contracts for high-priced coal have generally expired, that the supply of coal is more regular and that the price of coal has been reduced ten cents a ton, an order has been issued by the U. S. Fuel Administration making a flat reduction of 30 cents a ton for coke produced in by-product ovens except in the states of Alabama and Washington. The order became effective seven o'clock a. m., September 3.

Under the order the base price for by-product coke is fixed at \$5.70 for run of ovens and \$6.70 for selected foundry, which is a reduction of 30c. per ton from the former base price. Except where otherwise provided, the maximum prices, f.o.b. cars at point of production, for each grade of by-product coke shall be the sum of the base price for such grade, and the freight rate from the competing bee-hive coke district which takes the lowest freight rate to the point where such by-product coke is produced.

## The Terry Differential Flotation Process

THE Terry differential flotation process disclosed in U. S. Letters Patent No. 1,254,173, Jan. 22, 1918, and Canadian Patent No. 184,193, May 7, 1918, is based on the discovery that ammonia in solution promotes oxidation of metallic sulphides by air introduced into the pulp. An experiment illustrating the oxidizing influence of ammonia may be made by wetting clean pieces of iron with water and with ammonium hydroxide. Yellow ferrous carbonate soon forms on the iron wet with water while the piece of iron wet with ammonium hydroxide becomes bright red with ferric oxide. As the oxides of zinc, copper and lead are soluble in ammonium hydroxide and most ammonium salts, these sulphides are cleansed and their flotability is unimpaired, whereas iron oxide is insoluble and the oxide-filmed iron sulphide (pyrite or pyrrhotite) is rendered immune to flotation. As the air drives ammonia out of solution a closed tank and circulation system is the most economical in which to carry on the oxidizing reaction and conserve the volatile ammonia gas.

### FRACTIONAL PERCENTAGE OF AMMONIA REQUIRED

The amount of ammonia required to accomplish this result depends on the character of the ore, pulp dilution or density, time of contact and aeration. Solutions containing from 0.04 to 0.06 per cent  $\text{NH}_3$  were used in the test recorded in the accompanying data. Ammonium hydroxide or ammonia gas may be introduced directly into the pulp or generated *in situ* by decomposition of ammonium salts by alkalies, for example ammonium sulphate and sodium carbonate. The gas is rapidly absorbed or combined with the water forming ammonium hydroxide.

In treating some complex ores containing zinc, copper, lead and iron sulphides, ammonia may be introduced with the frothing agent in the form of an emulsion and good results obtained. With other ores this procedure fails to make a high recovery and it is found necessary to give the ore a preliminary treatment with ammonia and air before introducing the frothing agent.

In the differential flotation of some zinc-copper-iron sulphide ores it was found necessary to substantially remove the ammoniacal solution by decantation and replace with water before adding the frothing agent, otherwise copper sulphide would float with the zinc sulphide. Copper thus floated showed a marked tendency to drop as the ammonia was eliminated in cleaning and recleaning the concentrate and to appear in the midlings.

### NEUTRAL WOOD OILS BEST FOR AMMONIA PROCESS

When ammonia is introduced into ore pulp in conjunction with certain oils, no differential action is manifested and all sulphides are floated. This is particularly true with coal-tar distillates. The most suitable oils for differential flotation are found among the wood products, especially neutral pine oils and neutralized wood creosotes.

As the oxide film or coating on the iron sulphides is only superficial, the best results are obtained in flotation cells giving a maximum amount of aeration and minimum scouring action. This is characteristic of the Callow pneumatic cell. Of mechanical types, the K. & K.

machine is considered efficient. There is evidence but not conclusive proof that an iron machine gives better results than cells which are constructed of other metals or of wood.

A vast amount of valuable information has been acquired relative to differential flotation of metalliferous sulphides, as a result of research for a period of over two years, that can not consistently be given publicity at this time.

Although the accompanying data give some results of tests on zinc-iron sulphide ores, the process is applicable to differential flotation of other metalliferous sulphides, such as molybdenite and graphite, from iron sulphides.

#### SOURCES OF AMMONIA

Ammonia is derived from gas liquor byproduct in the manufacture of coal gas, ammonium sulphate or other salts by decomposition with alkalis. Ammonia is also

#### New Corrugated Concrete Roofing

Since the success of the asbestos-cement shingle has become well established, it is natural to expect larger fabricated parts to appear, which will occupy a place similar to corrugated iron. The British are now marketing this product. Their method of manufacture is reported to be as follows: Finely ground and cleaned asbestos fibre is mixed with portland cement in the proportion of about 1 to 6, and water enough added to make a dough. The material can be colored red with ochre etc. during mixing. The batter then flows on to a Fourdrinier machine of special design and a sheet formed on a felt.

Special waterproofing dopes are added similar to sizing in the paper industry and the sheets are then trimmed to size and corrugated. Special precautions have to be taken to see that the material does not squeeze thin at the tops of the corrugations, so that the

produced from calcium cyanamide or aluminium nitride by decomposition with superheated steam or by direct union of its elements under pressure (17 atmospheres), heat and a catalyzing agent as in the Haber process.

Aluminium nitride is manufactured from aluminium carbide, a byproduct in the electric smelting of aluminium ore (bauxite), and nitrogen from producer gases, or fractionated liquefied air. Calcium cyanamide is obtained by treating calcium carbide produced by fusion of carbon (powdered coal) and lime in an electric smelting furnace, with nitrogen gas as in the manufacture of aluminium nitride.

Ammonia liquor byproduct from coal-gas usually contains approximately 12 per cent NH<sub>3</sub> and has a market value of about ten cents per pound of ammonia content. The success of the Terry differential flotation process, like all others requiring additional agents, largely depends on the cost of such materials. Synthetic nitrogen products are now manufactured in large quantities, and afford a fairly cheap and abundant supply of this reagent.

product will be homogeneous as well as proof against breakage at weak spots. The sheets go from the machine to the seasoning shed, where the cement takes its initial set and cures without being disturbed. The pitch of the corrugations is made on the 3-inch basis similar to English corrugated iron, so that the product is flatter than the 2½-inch U. S. pitch.

Corrugated cement-asbestos sheets will be heavier than the metal ones but will be sufficiently durable for mechanical ware and will have the advantage of being far more resistant to atmospheric conditions, especially in chemical plants where acid fumes are present. It is to be hoped that a suitable synthetic siliceous fiber will be developed to take the place of the asbestos.

Imports of gold during the fiscal year 1918 amounted to only \$124,000,000 as compared with \$977,000,000 in 1917 while exports were valued at \$191,000,000 compared with \$292,000,000 in 1917. Silver imports amounted to \$70,000,000 in 1918 against \$35,000,000 in 1917, and silver exports, \$1,399,000.

# The Present Status of Electric Brass Melting\*

A Survey of the Application of Electric Furnaces to the Melting of Brass and Other Copper Alloys—Advantages and Disadvantages of Different Types—Central Station Viewpoint

By H. M. ST. JOHN

ELECTRIC brass-melting has for some time past been the subject of much technical discussion, presented from various points of view. The advantages of the process have been outlined and the progress made with different furnace types have been dealt with in detail by men well qualified to speak with authority. The writer has no desire to duplicate what has already been done so thoroughly. It seems possible, however, that certain fundamental principles, upon which the success of electric melting directly depends, have hardly received, at least in public, the consideration which they deserve. It is the purpose of this paper to discuss these fundamentals, with particular attention to the bearing which they have upon electric-furnace design, and to trace the development of the various furnace types proposed for electric brass-melting, which have succeeded or failed, dependent upon the degree to which these basic principles have been recognized and followed. Finally, it is desired to emphasize the financial interest which the central station industry has in the ultimate success of the electric brass-furnace, and the importance of the part which this industry can take in directing the development of electric melting along sane and rational lines.

## THE FIELD OF ELECTRIC BRASS MELTING

In 1914 it was estimated by Gillett<sup>†</sup> that there were, in the United States, at least 3600 plants engaged to some extent in melting brass and bronze. It was further estimated that the value of the metal annually melted by these plants was in the neighborhood of \$120,000,000, and that, of this total, the value of the metal lost beyond recovery during the melting operation was not less than \$3,000,000.

When one considers the extensive use of brass and bronze in warfare, and the enormous industrial expansion along metallurgical lines which has taken place in this country since 1914, it becomes evident that an estimate made on the basis of present conditions would name figures much larger than those stated in 1914. Even if the total tons of metal melted annually were no greater now than then, the increase in market value of the metals concerned would of itself nearly double the value of the metal produced. An avoidable waste of metal which was then considered important has ever since deserved and received, in constantly increasing degree, the attention of our metallurgists.

It has long been known that it is theoretically possible to eliminate much of this loss by the use of electric melting, particularly in the case of yellow brass and other alloys high in zinc. Most of the electric-furnace

development in the copper-alloy field has been carried out with this end in view. Metallurgically speaking, the problem is not a simple one and progress has been rather slow. Important advances have, however, been made since 1914, and the present outlook warrants a considerable degree of optimism.

Two widely different types of electric furnace are now on the market and in commercial use for melting yellow brass, one highly efficient but limited in its use to a portion of the field only, the other less efficient but otherwise more widely applicable. At least one other type of furnace has been experimentally successful and is re-

AJAX-WYATT VERTICAL-RING INDUCTION FURNACE

ported as about to enter the commercial field. Two or three additional types are being actively developed and give some promise of eventual success. So far as yellow brass is concerned, it cannot be said that an entirely satisfactory furnace has yet been produced, but the field has been partially covered, and the prospects for further advancement in the art are good.

Previous to the war the use of electric furnaces for melting copper alloys did not seem feasible except in cases where a large metal saving helped to counterbalance the higher cost of electric heat. Under present conditions the high cost and poor quality of crucibles, the high cost and shortage of important metals, the high cost and scarcity of labor, and the insistent demand for a high rate of production at any cost, are factors which combine to make electric melting profitable in

\*Read before the Ohio Electric Light Association.  
†H. W. Gillett: "Brass-furnace Practice in the United States," Bureau of Mines Bulletin No. 73, page 9 (1914).

many cases where it would previously have been unprofitable. Whether electric-furnace installations which owe their existence to these peculiar conditions will continue to show a profit when normal conditions once more prevail, is still an open question. No one can say when

conditions will again become normal, or, for that matter, what sort of conditions will be considered normal in the future. Much will depend upon the progress made in furnace design, and in operating methods, during the continued existence of the economic conditions which at present make possible the electric melting of copper alloys containing little or no zinc. The necessary progress can only be made by the combined efforts of such individuals and companies as

are now profiting, and expect to profit in the future, from the increased use of electric furnaces.

#### ADVANTAGES OF ELECTRIC MELTING

Electric heat is expansive at best, and, although it can be applied much more efficiently than heat derived from fuel, especially at high temperatures, it cannot profitably be employed except in cases where its use makes offset its added cost. The advantages which may naturally be expected to accrue from electric melting, as compared with melting in fuel-fired furnaces, are roughly as follows:

1. *Metal Saving.* The saving of metal, otherwise unavoidably lost, is the principal economic advantage which the electric furnace is required to show in the melting of copper alloys, particularly in melting yellow brass. It has been completely demonstrated that such a saving can be made in the electric furnace, by virtue of the fact that the furnace chamber can be tightly closed during the melting period, and a neutral or reducing atmosphere maintained. As we shall see later on, it does not follow that every electric furnace is capable of a favorable performance in this respect. Conditions resulting from the war have greatly accentuated certain other advantages of electric furnace operation, but in more normal times no electric furnace can hope to succeed in this field unless its use results in a saving of metal as compared with fuel-fired practice.

2. *Improved Quality.* It has been found, in most cases, that a more uniform quality of metal can be produced in the electric furnace than in fuel-fired furnaces operating under similar conditions, and that it is easier to produce an alloy of closely specified composition. In

general, these advantages can be accepted as inherent in properly conducted electric furnace operation, resulting from the greatly reduced loss of volatile metals and from the elimination of contaminating combustion gases. So far as copper alloys are concerned, it is still undecided whether or not a higher quality of metal can be produced in the electric furnace, as compared with the best of fuel-fired practice. It is beyond question that high quality can be achieved more easily and certainly. The successful electric furnace must be at least as satisfactory in these respects as the best fuel-fired furnace.

3. *Exact Temperature Control.* The production of perfect castings with the least possible number of defectives depends in large degree upon the use of metal at a temperature which conforms closely with that known to be most favorable for the work in hand. The electric furnace lends itself readily to exact temperature control and thereby enjoys an important advantage.

4. *Increased Production.* In general, the speed of melting is greater in electric furnaces than in fuel-fired furnaces, because of their higher operating temperature and greater efficiency. The electric furnace can also be used in larger units than is commonly the case with fuel-fired furnaces.

5. *Elimination of Crucible Cost.* The cost of crucibles is a considerable item even in normal times. Under present conditions this cost is very high. Electric furnaces which use no crucibles eliminate this expense. Large fuel-fired furnaces effect the same saving but, from a metallurgical point of view, are seldom as satisfactory as fuel-fired crucible furnaces. Electric crucible-furnaces deserve little consideration at the present time.

6. *Incidental Savings.* The operation of large units results in an economy of floor space and of labor, dependent upon the use of large electric furnaces where

Courtesy The McGraw-Hill Book Co.

large fuel-fired furnaces are not practicable. Increased production results in decreased overhead and interest charges per ton of metal turned out.

7. *Better Working Conditions.* More favorable conditions for the workmen, tending to increase their efficiency as well as their comfort, result when excessive heat, noise, and fumes are eliminated. The properly selected and correctly operated electric furnace is almost ideal in this respect. In installations where the reverse is true, the trouble is due to the use of an unsuitable furnace, or to careless operation, or to both of these as contributing causes.

It should not be understood that these advantages necessarily follow from the use of any electric furnace which may happen to be selected. The furnace must be of suitable type, properly designed and correctly used. A misapplied electric furnace may prove worse in almost every respect than the fuel-fired furnace which it replaces.

#### REQUIREMENTS OF ELECTRIC MELTING

First consideration must always be given to metallurgical requirements. No electric furnace can achieve success unless it performs satisfactorily the function which is expected of it, no matter how efficient it may be nor how admirable its design may appear in other respects. Unless the design is metallurgically correct, the furnace is useless as an industrial tool.

Steel may be classed as a peculiarly "stolid" metal; it melts at a high temperature, and it may be heated as rapidly as you please during the melting operation, providing it is not exposed to contaminating elements during the process. With copper alloys the case is quite otherwise. Copper itself is somewhat volatile and oxidizes much more readily than steel, when in the molten state. Lead is somewhat volatile—more so than copper—and oxidizes very easily. Zinc is exceedingly volatile at molten-brass temperatures. All copper alloys must be treated carefully during the melting process in order that losses of metal by oxidation and volatilization may be kept at a minimum.

Yellow brass for thin castings must be poured at a temperature not far below its boiling point in order that the metal may be sufficiently fluid. At this temperature, zinc, which comprises 30 to 35 per cent of the alloy, has a tendency to vaporize rapidly. So long as the metal is contained in a tightly closed furnace chamber, which can easily be done in the electric furnace, this tendency is counter-balanced by the vapor pressure of the metal which has already been vaporized and with which the furnace atmosphere is saturated. When the furnace is opened for pouring the metal, or for any other purpose, the vapor pressure is released and further quantities of zinc will escape from the metal without restraint. If the heating has been perfectly uniform and all portions of the melt are at approximately the same temperature, the loss of zinc which ensues will constitute an unavoidable minimum. If the heating has not been uniform, some portions of the melt will be at a temperature higher than the desired pouring temperature, and such portions will lose zinc at a higher rate. If the lack of temperature uniformity is very great the loss which occurs after the furnace is opened, and during pouring, will be decidedly excessive. In fact, some portions of the metal may be so seriously overheated during melting that the high vapor pressure formed within the furnace will force considerable quantities of zinc vapor through crevices in the furnace structure. In some cases it may be practically impossible to keep the furnace chamber closed, even to a reasonable degree. Under such conditions the zinc losses are likely to be quite as serious as in fuel-fired crucible furnaces, or even more so.

What is true of yellow brass poured at a temperature near its boiling point is also true, although in less degree, of yellow brass poured at lower temperatures, and of other copper alloys. The lower the percentage of vol-

atile metal the more easily the alloy will stand up under uneven heating. But it can be accepted as an axiom of copper-alloy melting that heat must be applied to the metal as uniformly as possible, whether the alloy under treatment is a brass, a bronze, or some one of the less common alloys. If the application of heat in the furnace lacks uniformity to a serious degree, an excessive loss can only be prevented by some method of stirring

INDIRECT ARC FURNACE  
From Stansfield, "The Electric Furnace"  
Courtesy The McGraw-Hill Book Co.

the metal, and this stirring must be effected within the furnace, without opening the furnace doors.

The metal as poured from the furnace must be uniform in composition, with its various constituent metals thoroughly well mixed and alloyed. In some cases a rigidly specified composition must be closely met. The finished casting or ingot must be of a quality at least as good, with respect to strength, freedom from cracks, blowholes, etc., as that obtainable from fuel-fired crucible furnaces.

Since electric heat is more costly than that derived directly from fuel, it is important that the thermal efficiency of the electric furnace should be as high as can be obtained consistent with other requirements. A high thermal efficiency in electric melting, unless heat is generated in the metal itself, requires a high-temperature heat source, located as close as may be to the metal, under conditions which offer the least possible opposition to the flow of heat from the source to the metal. At the same time the walls of the furnace must be sufficiently thick and of high heat-insulating quality in order that heat may not be dissipated uselessly from the outer walls.

In some furnace types these requirements are directly opposed to the metallurgical requirements already considered. In such cases thermal efficiency must be sacrificed to as great a degree as may be necessary in order to satisfy the metallurgical requirements. The highest efficiency consistent with good metallurgical results should be maintained; any higher efficiency is false economy. Of course, other things being equal, the more efficient type of furnace will meet with greater success.

The electric furnace, to reap the full benefit of its economic possibilities, must operate in large units and must not use crucibles. The higher its speed of melting the better, so long as speed is not detrimental to metallurgical results.

The electrical characteristics of the furnace must be such as to make it a desirable load for the central station company or the factory power plant. Its power factor must not be abnormally low and its power fluctu-

ations must not be so violent as to endanger transformers and other electrical equipment, or to interfere with satisfactory service to other customers of the central station company who may be connected to the same power line.

It seems hardly necessary to add that the successful electric furnace must be sturdy and reliable, quite as capable of performing its function, day in and day out, under regular operating conditions, as are the best types of fuel-fired furnaces. The furnace and its adjustments should be as simple as possible, although with

through molten metal, previously melted in some other furnace.

The "pinch-effect" direct-resistance furnace was the first to utilize this principle. In this type the circuit consists of two or more vertical or inclined resistor channels in the hearth of the furnace, terminated at the lower end by electrodes, and opening at the upper end into the main portion of the metal bath, which conducts the current from one resistor channel to another. The resistor channels are so designed as to length and cross-section that the pinch phenomenon occurs in them continuously during operation. The resultant effect is a constant stream of hot metal issuing from the resistor channels, with considerable force, into the metal bath above, while colder metal flows down to take its place and is heated and ejected in its turn. Virtually all of the heat is generated in the molten metal temporarily designed for steel melting have been tried, but no new type of direct-arc furnace has been developed for this specific purpose. No furnace of this general type has ever succeeded in satisfactorily melting yellow brass, or other copper alloys containing an appreciable percentage of zinc. The high-temperature heat source in direct contact with the bath overheats the metal in its immediate vicinity and invariably causes an excessive loss of zinc.

With copper alloys containing no zinc the case is somewhat different, since lack of uniformity in heating is less likely to result in serious loss. In a direct-arc furnace of small size it has been found possible to melt a copper alloy containing as much as 15 to 20 per cent lead at a loss less than that commonly experienced with the same alloy in fuel-fired crucible furnaces. In larger furnaces the greatly increased rate of heat input supplies heat to the metal, in the neighborhood of the arc, more rapidly than it can be conducted away to more distant portions; the surface of the metal becomes overheated while other parts of the bath are still much below the desired temperature.

The direct-arc furnace has the advantage of simplicity and high thermal efficiency; its design has been more highly developed and perfected than that of most other electric furnace types and, since it is so widely used in the steel industry, several furnace designs are on the market, reliable and readily available. It is very doubtful, however, if any direct-arc furnace deserves wide application for melting copper alloys. Its use is limited to only a few of the common alloys, and, if large units are employed, the metal loss, even with these alloys, is likely to be serious. Small units are more satisfactory in this respect but are subject to the disadvantages of lower efficiency, higher fixed charges, and higher operating costs per ton of metal produced.

Such direct-arc furnaces as are now in use in this field—and there are a few—hold their place by virtue of their simplicity, elimination of crucible cost, and their high rate of production, at a time when these qualities are at a premium.

#### INDIRECT-ARC FURNACES

The intensity of heat application to the metal is lessened somewhat by using an arc between two or more independent electrodes above the bath, heating the latter by direct radiation. This is the principle of the usual type of indirect-arc furnace. The arc does not come in

BAILEY INDIRECT RESISTANCE FURNACE

a large electric furnace it is permissible, and nearly always desirable, to use a higher grade of operator than would be employed to tend fuel-fired crucible furnaces.

#### FURNACE DEVELOPMENT

A great variety of electric furnace types have been proposed and tried out for melting brass. It is hardly an exaggeration to say that every known method of applying electric heat to a metal has been utilized by one or another of the various designs which have reached at least an advanced experimental stage. Some of these types have been eliminated as inherently unsuited for the purpose; some have been abandoned because of difficulties which may eventually be overcome by other investigators; others, partially successful, have apparently reached the height of their development; still others seem to possess greater possibilities of ultimate success than have yet been demonstrated.

#### DIRECT-RESISTANCE AND INDUCTION FURNACES

The most obvious method of reaching a high thermal efficiency without overheating the alloy is to generate heat in the metal itself by the passage of an electric current through it. This may be done either by means of a direct-resistance furnace, in which electrical contact with the metal is made through electrodes, or by means of an induction furnace, in which case the metal forms a complete circuit for the flow of an induced electric current, without the use of electrodes. In either case it is practically necessary to establish the circuit

direct contact with the metal and the latter forms no part of the electric circuit. It is apparent that in this type of furnace the surface of the metal is not so seriously overheated as in the direct-arc furnace, but such overheating as exists is, nevertheless, too severe to permit the use of such furnaces in melting yellow brass. The indirect-arc furnace can be used economically with alloys containing 5 to 10 per cent of zinc, possibly as high as 20 per cent, but certainly not for higher values.

The design of the indirect-arc furnace is invariably somewhat more complicated than is the case with the direct-arc furnace, and its thermal efficiency is not so high, but, in the melting of copper alloys, it can be economically used in larger units, and seems to be, in general, a more satisfactory tool for the purpose.

Several indirect-arc furnaces are now in use in this country for melting copper alloys which contain small percentages of zinc or none at all.

In a new type of indirect-arc furnace,<sup>2</sup> the metal, as soon as it becomes molten, is agitated by rocking the furnace mechanically, in order to avoid overheating of the surface layer. In this way non-uniformity of heating is largely rectified, and it is possible that alloys high in zinc can be melted without excessive loss. The furnace has received a comprehensive commercial test, and, according to report, will soon be placed on the market. This type gives considerable promise of success and should be applicable to a wide field of alloy melting.

#### INDIRECT-RESISTANCE FURNACES

Resistance furnaces which do not utilize the metal itself as an electric resistor may be grouped in three classes: (1) Those which radiate heat directly to the metal, similar in principle to the indirect-arc furnace, (2) those which radiate heat to the furnace roof and thence to the metal by reflection and secondary radiation, (3) those which feed heat to the metal by conduction through a refractory wall.

Heating by direct radiation is the most desirable of the three from the standpoint of efficiency. For this purpose it is practically necessary to support the resistor above the bath in some manner, and this has never been done successfully in furnaces of any considerable size. In small furnaces it has been possible to utilize this principle and to melt brass satisfactorily without overheating the surface of the metal to an undesirable degree, since, as compared with an arc, the resistor has a large area and operates at a much lower temperature. At the same melting speed the application of heat to the metal is more uniform but the efficiency is somewhat less.

This type of furnace is applicable to yellow brass but is not in commercial use because of the mechanical difficulties involved in its construction. The possibility of its eventual use depends upon the development of a resistor material which is at once highly refractory, homogeneous, mechanically strong at high temperatures, and possessed of a fairly high electrical resistance at the working temperature of the furnace.

The second type named ranks next in the order of thermal-efficiency. In this design a refractory wall separates the resistor from the metal—although not necessarily in contact with the metal—and the major portion of the heat is radiated from the resistor to the

furnace roof, the latter acting as a secondary heat source which reflects and radiates part of the heat which it receives to the bath beneath it. The heat has to travel rather a long path and much of it is lost by the wayside. As a result, the furnace is not so efficient in principle as those previously discussed. In order to stimulate a reasonably rapid flow of heat the resistor element must be much hotter than the roof, and the roof, in turn, much hotter than the metal. Thus the possibility of a high rate of production depends upon the use of a resistor capable of operating at a temperature very much above that of the metal, even at the pouring point. The furnace roof must be exceedingly refractory and the brickwork in the immediate neighborhood of the resistor must be even more refractory than the roof. In the present state of the art these conditions are difficult to meet, and the production speed of this type of furnace is consequently somewhat limited.

The furnace, in common with other indirect resistance furnaces, contends with another disadvantage, somewhat minor in character but worth considering, which is not found in direct-resistance furnaces nor, to any great degree, in arc furnaces. The heat storage of the furnace is large and the stored heat is at a temperature higher than that of the metal. As a consequence, the temperature of the metal will continue to increase after power has been shut off. When the metal has reached its desired pouring temperature it must be poured promptly in order to avoid overheating. It is often impossible to hold the molten charge in the furnace, even for a few minutes, without serious metal loss.

This is the only form of indirect-resistance furnace which has found commercial use for melting copper alloys. In its present form, it is simple, reliable, easy to operate, and can be used on practically any alloy, for either intermittent or continuous operation. Its metal-

COMBINATION ARC AND RESISTANCE FURNACE

lurgical characteristics are excellent, with the single exception that it is somewhat difficult to secure thorough mixing, and it is especially suitable for melting alloys high in zinc. Its production rate is not rapid and it is not so efficient as the furnace types already described.

A similar type of furnace utilizes a combination of arcs and resistance elements, all radiating heat to the furnace roof, which, as in the furnace just described, serves as a secondary heat source. The use of arcs makes possible a considerably higher power input, more rapid

<sup>2</sup>H. W. Gillett and A. E. Rhoads: "A Rocking Electric Brass Furnace," *Met. & Chem.*, Vol. LXIII, No. 11 (1915), page 582.

melting, and probably a slightly more favorable efficiency, provided a sufficiently refractory roof is used. A very high efficiency cannot, however, be expected from this type of furnace. Certain difficulties in furnace design have been encountered which have so far postponed the commercial use of this furnace. It has been under test for some time, but the results obtained have not yet been made public.

The least efficient method of transferring heat from its source to the metal is to force it through a refrac-

use. It is possible that, in cases where perfection of metallurgical results is by far the most important consideration, an electric crucible-furnace can profitably be employed, but, so far as known to the writer, no commercial installation of this kind exists.

So far as thermal efficiency is concerned, the crucible furnace takes its place at the bottom of the list. Its energy consumption per ton of metal produced is about three times that of the induction furnace. One or two attempts have been made to improve the efficiency by constructing a multiple-crucible furnace, with resistor elements suitably arranged between crucibles. In this way it is possible to make a substantial gain in efficiency, but there are serious objections to this type of construction and its development has been dropped.

#### PRESENT STATUS OF ELECTRIC MELTING

We find, then, that there are four types of electric furnace in commercial use for melting copper alloys. Of these, only two are suitable for use with alloys high in zinc. One, the vertical-ring induction furnace, is of high efficiency, but somewhat limited as to its application and not sufficiently flexible for general foundry use. Within its limited range it appears to be giving very satisfactory results. The indirect-resistance, indirect-radiation furnace is less efficient and has a lower rate of production in proportion to its holding capacity, but is more flexible and better suited to general foundry use. Neither of these furnaces can be classed as altogether satisfactory but each is serving a useful purpose.

The indirect-arc furnace is in use for melting alloys which contain small percentages of zinc and those which contain no zinc at all. It is more efficient than the indirect-resistance furnace and, within its field, more flexible than the induction furnace.

The direct-arc furnace is being used, to a limited extent, in melting copper alloys which contain no zinc. Present conditions make its use profitable in some cases, but its continued application for this purpose is not assured.

The most promising possibilities, not yet in commercial use, are, first, a form of induction furnace which will be, not only efficient, but also flexible and capable of widespread application, and, second, a form of arc furnace which will be applicable to yellow brass and other high-zinc alloys, as well as to the less sensitive alloys. Able efforts are being made to reach both of these goals. There may be some hope, eventually, of an indirect-resistance, direct-radiation furnace which will be commercially useful, but at present no steps are being taken to perfect such a type.

Electric crucible-furnaces, which are at once reliable and effective, can be built and, in fact, have found some commercial use for melting precious and semi-precious metals. In the field of copper alloys, there seems little prospect that their use will ever be profitable except, perhaps, to a limited extent, under out-of-the-ordinary conditions.

#### THE CENTRAL STATION VIEWPOINT

If all the brass and bronze produced in the United States were to be melted in electric furnaces the annual consumption of electric energy for this purpose would be in the neighborhood of 200,000,000 kilowatt hours, and the generating capacity required to supply the neces-

HELBERGER RESISTANCE FURNACE  
From Rodenhauer's "Electric Furnaces"  
Courtesy of John Wiley & Sons

tory wall, even though this wall be that of a clay-graphite crucible, a mixture which has a fairly high heat conductivity. Theoretically, the least undesirable arrangement under these conditions is to enclose the resistor in the refractory wall or to use the wall itself as a resistor. In the latter case the wall must be separated from the metal by an insulating layer to prevent short circuiting. It is not an easy matter to make this insulation permanent and this factor has been a serious source of difficulty. A resistor enclosed in a refractory wall tends to reach excessively high internal temperatures, and no material has yet been found, satisfactory in other respects, which will not destroy itself under these conditions. Another troublesome difficulty results from the ease with which most resistor materials unite chemically with the furnace refractories at high temperatures, thereby destroying both themselves and the refractories. Some two or three furnace types have been designed to make use of this principle, but they have been uniformly unsuccessful. There is at present no real activity along this line.

#### ELECTRIC CRUCIBLE-FURNACE INEFFICIENT

Finally, it is possible to melt brass in a crucible by means of resistor elements which surround but do not touch the crucible. Perhaps the most perfect results, from a metallurgical standpoint, can be obtained in this manner, but thermal efficiency is at a minimum and, in any case, the electric crucible-furnace lacks most of the secondary advantages upon which the electric brass-melting furnace must depend in part for its successful

sary power would be about 75,000 kilowatts. There is little reason to expect the complete electrification of this industry, either now or in the future, but the expansion in this field which may reasonably be predicted is sufficiently large to be interesting to the central station companies.

The central station not only has an object in promoting the satisfactory progress of this development, but has at stake interests which can only be protected occupying these channels or tubes. The main portion of the metal, occupying the furnace chamber above, is heated by contact with the hot metal, and solid metal added to the bath is melted by the same means.

The stirring action of the moving streams of metal is vigorous and the temperature of the main portion of the bath rises uniformly. There is no difficulty in restraining the vaporization of zinc, and, in fact, it may be said that the metallurgical requirements of any single alloy are almost perfectly fulfilled.

Generation of heat in the metal itself, where its presence is desired, is theoretically ideal from the standpoint of efficiency, since no part of the furnace is any hotter than the metal, and wall losses are reduced to a minimum. In this case, however, another factor tends to reduce the efficiency. The operating voltage of the furnace is necessarily very low and the current correspondingly high. The massive metallic electrodes are excellent conductors of heat and require a considerable degree of water-cooling. In this way a large quantity of heat escapes from the furnace, and the thermal efficiency is much lower than would otherwise be the case.

Considerable difficulty has also been experienced in constructing satisfactory transformers for use with such extremely low voltages and high currents as are required.

The next step in this development was the application of a similar principle to the induction furnace. This eliminated the use of electrodes and the troublesome transformers, since the furnace now served as its own transformer. In this design the resistor channels meet at their lower end, two of them forming a single V-shaped resistor, opening as before into the metal bath above. The generation of heat takes place as before in the resistor channels, and the same vigorous circulation of metal results. Whether this action is now due primarily to the pinch phenomenon, or to a motor effect resulting from the flow of current through the continuous molten resistor, is open to question. It is difficult to tell where one phenomenon leaves off and the other begins.

The thermal efficiency of this furnace, operating, as it does, without electrodes, is very high, probably higher than that of any other electric furnace ever tried out for copper alloy work. Its metallurgical characteristics are also excellent. It offers a perfectly steady, uniform load at a power factor which is satisfactory, at least in the relatively small sizes so far built, the largest taking a 60-kw. input and pouring 600 lb. of metal per heat. In larger sizes there might be trouble with low power factor, as is so frequently the case with large induction furnaces.

The furnace is in commercial use and is said to be giving satisfactory results. It has, however, pronounced limitations which are partly inherent in its design and partly remediable. Its small size is one disadvantage

but it is probable that somewhat larger sizes can be successfully built. It has not so far been found practicable to use the furnace with alloys high in lead, because that metal has a tendency to penetrate minute cracks in the lining of the resistor channels, causing short circuits. The remedy for this awaits the development of a lining especially suited for use with lead.

#### LIMITATIONS OF INDUCTION FURNACE

The more serious limitations of the furnace are its lack of flexibility in changing from one alloy to another and the practical necessity of operating it continuously, allowing the furnace to cool not oftener than once a week. The length and cross-section of the resistor channels are especially designed to accord with the electrical resistance—in the molten state—of the alloy which is to be used. The same resistor channels cannot be employed with another alloy of widely different resistance, which, accordingly, requires the installation of new channels of properly modified design. In changing from one alloy

HOSKINS CRUCIBLE FURNACE

to another, even if the resistance is approximately the same, it is necessary to pour the furnace clean and start with a molten charge of the new alloy, melted in another furnace.

The linings of the resistor channels stand up very well under continuous use but deteriorate rapidly under the daily heating and cooling of ten-hour day operation. This can be obviated by maintaining over night sufficient power to keep the channels filled with molten metal, which, of course, results in some addition to the cost of operation.

The limitations described tend to prevent the use of this furnace in commercial foundries, which melt a wide variety of alloys and do not work nights, but form no bar to its use in yellow-brass rolling mills, to the purposes of which it seems well suited.

#### NEW DESIGN OF INDUCTION FURNACE

There has been proposed a new design of induction furnace which would not be subject to these limitations. In this type a spark gap and an arrangement of condensers connected in series and in parallel are used in the primary circuit of the furnace, which operates at about 10,000 volts and some 15,000 to 20,000 cycles. The secondary of the furnace consists of a crucible or melting chamber with electrically conducting walls; the

metal within the crucible also carries part of the secondary current, to a minor degree when it is first charged in the form of solid pieces, to a much greater degree when it becomes molten. The primary circuit is arranged around the melting chamber and separated from it by suitable refractory and heat-insulating walls. The furnace is, in a sense, an eddy-current rather than an induction furnace, since no iron cores are used and the metal itself, lying in a circular pool, completely short circuits what, in an induction furnace, would be called the secondary circuit. This unique arrangement is made possible by the exceedingly high frequency used.

At last accounts this furnace had only been built in very small sizes, capable of pouring not more than 45 lb. of metal per heat. It is understood that the furnace is being developed energetically and it is possible that larger sizes have been built during the past six months. The design is so new and unusual that it is difficult to predict the performance of larger sizes, as to efficiency, power factor etc. There is no apparent reason why the metallurgical characteristics should not be good, and the construction of the metal-containing portion of the furnace is desirably simple. It is obviously unnecessary to use molten metal in starting the furnace. Any alloy or even nonconducting material, such as glass, can be melted without changing the furnace design. The furnace is suitable for intermittent operation and need not be kept hot overnight.

#### ARC FURNACES

Next to the methods already described the most direct way of applying heat to the metal is by means of an outside heat source in direct contact with the bath. The direct-arc furnace is the only type which utilizes this principle.

The application of direct-arc furnaces to copper alloy melting has been rather limited. One or two furnaces by a constant oversight of such features of the development as directly concern itself. For example, all furnaces are not equally satisfactory from the standpoint of economical power supply, and the power company which expects to furnish power for an electric furnace installation should, for its own sake, be familiar with the electrical and operating characteristics of the furnace.

There is an even more vital point to be considered. The central station company sells to its customers a raw material, electric energy. Electric energy must always be converted into some other form of energy by the customer before it is of the slightest use to him. Various devices are used to convert electric energy into heat, light, mechanical energy, or chemical energy. The electric furnace is such a device. These converting devices are customarily purchased, operated, and controlled by the customer. The success of his business depends in part upon their proper selection and correct use. But the success of the central station company also depends upon the proper selection and correct use of the customer's equipment, since the customer's use of the company's service cannot possibly be a satisfactory one if its method of application is faulty. This may be a matter of minor importance insofar as it concerns the use of motors and other well standardized equipment; it is a matter of great importance when it involves new electrical devices or new processes which are not well under-

stood and are, perhaps, entering the industrial world in a somewhat crude and undeveloped form.

Not all electric furnaces are good. Good electric furnaces can be misapplied. Such misapplications have been made and are now being made. Good electric furnaces, properly applied, may result in failure because of faulty operation. This, too, has happened. When such a failure occurs three parties suffer. The user of the furnace has lost some money, but he can go back to his old practice and use a fuel-fired furnace. The seller of the furnace has lost a customer, but he can find another, a few hundred miles away, who has never heard of the failure. The central station company has lost an opportunity to extend a profitable phase of its business. Every such failure becomes town talk, in an industrial sense, in the community in which it has occurred, and makes it increasingly difficult to promote the use of electric furnaces in that locality. The business of the central station company is generally limited to a relatively small territory, and its loss of possible future profits is correspondingly greater, because more concentrated, than that of the seller of electric furnaces.

The central station industry has something to gain by the successful development and use of electric furnaces, it has something to lose by their failure. It is in a position to protect this interest if it cares to do so. The central station company can, by virtue of a little effort, inform itself quite fully concerning the possibilities of electric furnace application within its territory. It can, in a similar way, make itself familiar with such requirements of its customers as have a bearing on electric furnace use. It will then have a wider knowledge than its customers of the electric furnace situation at large; it will have a more detailed knowledge of electric furnace possibilities and requirements within its territory than has the electric furnace salesman. By proper use of this knowledge and of such influence as it ought to possess in the industrial community which it serves, the central station company can promote well advised applications, prevent misapplications, point the way to correct use, discourage incorrect use, and insure the profitable development, within its field of operations, of this newest of electric load builders, the electric furnace.

Commonwealth Edison Co.,  
Chicago, Illinois.

#### Chemists Needed in War Industries

Provision has been made through an order of the Secretary of War dated May 10, 1918, by which manufacturers of material necessary to the prosecution of the war, who have lost the services of chemists through the draft, may again obtain these men for war work.

Provision has also been made whereby manufacturers threatened with the loss of their trained chemists in the present draft may retain these men. Only those chemists, however, whose services are necessary to war work, will be considered and the evidence submitted by the manufacturer must be conclusive.

Manufacturers thus affected should apply to the Industrial Relations Section of the Chemical Warfare Service, U. S. A., Unit F., Seventh and B Streets, Washington, D. C., for the regulations governing men already drafted, or the possible reclassification of men not yet called.

# Aluminium and Its Light Alloys—III

## The Constitution and Properties of Aluminium Alloys with Copper, Iron, Manganese, Nickel, Silicon and Zinc—Aluminium-Zinc Alloys Lost Tensile Strength with Increase in Temperature

By PAUL D. MERICA

### IX. INVESTIGATION OF ALLOY SERIES 1. ALUMINIUM-COPPER

THE constitution of these alloys has been studied by Gwyer (378), Carpenter and Edwards (381), Curry (382), and Guillet (384, 385). On the aluminium side of the constitution diagram a compound,  $\text{CuAl}_3$ , is formed which is partially soluble in aluminium; the exact solubility has not been determined but is undoubtedly not far from 3 per cent of copper. The eutectic of aluminium and  $\text{CuAl}$ , is at 32 per cent copper and 545 deg. C. No thermal transformations have been noticed below the eutectic temperature.

The principal research on this series of alloys is that by Carpenter and Edwards, who in addition to their studies of the constitution of this system contribute results of mechanical and corrosion tests, given below.

The tensile properties of these alloys as sand and chill cast are shown in Figs. 12 and 13. It is noted that the tensile strength of the alloy increases with the increase of copper content. The alloy containing 8 per cent of copper is one very commonly used in the alu-

of 1½ in. From this rod portions were hot rolled to 1⅜ in. diameter and drawn after annealing to 1⅜-in. diameter. From 0 to 8 per cent of copper, all of the alloys rolled well, and from 0 to 4 per cent of copper they could be drawn sound. In Fig. 14 are shown the results of the tests of 1½-in. diameter hot rolled bars. The bars rolled to 1⅜-in. diameter showed throughout a higher tensile strength than those rolled to 1½ in., amounting to from 2000 to 3000 lb. per sq.in. The bars drawn with and without annealing showed a higher tensile strength but also a smaller elongation. In Table 8 are shown the test results of an alloy containing 3.76 per cent of copper in different conditions.

FIG. 12.—TENSILE PROPERTIES OF ALUMINIUM-COPPER SAND CAST ALLOYS (CARPENTER AND EDWARDS)

FIG. 13.—TENSILE PROPERTIES OF ALUMINIUM-COPPER CHILL CAST ALLOYS (CARPENTER AND EDWARDS)

minium casting industry to-day. Tests were made upon sand castings to ascertain the effect of heat treatment, consisting of quenching from 450 deg. C. and annealing at 450 deg. C. The alloy containing 8.08 per cent of copper showed, as sand cast, a tensile strength of 16,600 lb. per sq.in. with approximately 2 per cent elongation; as sand cast and annealed a tensile strength of 15,900 lb. per sq.in.; and as sand cast and quenched, 18,000 lb. per sq.in. Quenched alloys were consistently higher in tensile strength than the cast or cast and annealed alloys.

Ingot 3 in. in diameter and 20 in. long were heated to 400 deg. C. and rolled in round grooves to a diameter

Sheets were rolled from an ingot 6½x9½x½ in. by hot rolling at ¾ in., allowing to cool, and cold rolling to ½ in. The resulting slab was then cut into portions and the portions rolled down to different thicknesses with intermediate annealing. In Fig. 15 are shown the results of tests upon a sheet rolled to 0.05 in. in thickness. The tensile test results on these sheets are very similar to those obtained on the same alloy in the form of rolled or drawn bars. The authors draw the conclusion that there is nothing to be gained by adding more than 4 per cent of copper for rolling or forging alloy, as well as for a casting alloy. Their conclusion as regards the casting alloy is not in accord with modern practice,

which favors the use of an alloy containing 8 per cent of copper.

Plates cut from rolled sheets of copper contents varying from 0 to 5.34 per cent were exposed for 62 days to the action of both seawater and fresh water. Those exposed to fresh water were slightly corroded but gained in weight due to the coating of aluminium hydrate formed. Those exposed to the action of sea-water were

FIG. 14.—TENSILE PROPERTIES OF ALUMINIUM-COPPER ALLOYS; 1½-IN. HOT ROLLED BARS (CARPENTER AND EDWARDS)

badly corroded and pitted; the losses in weight are given below:

| Per Cent Copper | Loss of Weight in Sea-water; Lb. Per Sq. Ft. Per Month |
|-----------------|--------------------------------------------------------|
| 0.00            | 0.008                                                  |
| 0.93            | 0.008                                                  |
| 1.57            | 0.008                                                  |
| 2.36            | 0.007                                                  |
| 3.74            | 0.005                                                  |
| 4.74            | 0.004                                                  |
| 5.34            | 0.003                                                  |

The loss of weight is considerable, for the first three

FIG. 15.—TENSILE PROPERTIES OF ALUMINIUM-COPPER ALLOYS; PLATES 0.05 IN. THICK (CARPENTER AND EDWARDS)

alloys, about 3½ times that which would be experienced by mild steel under the same conditions.

It is concluded that these alloys are not suitable for construction which will be exposed to sea-water.

## 2. ALUMINIUM-IRON

Gwyer (390) has studied the constitution of this system. On the aluminium side a compound,  $\text{FeAl}_3$ , is formed which gives a eutectic with aluminium at practically 0 per cent iron, at 649 deg. C. The compound is not appreciably soluble in aluminium.

Schirmeister below gives the results of some mechanical tests of iron-aluminium alloys.

## 3. ALUMINIUM-MAGNESIUM

Grube (402) has investigated the constitution of the aluminium-magnesium alloy series and has found that a compound,  $\text{Al}_2\text{Mg}_3$ , is formed, melting at 465 deg. C. This compound forms a eutectic with aluminium at 453 deg. C. and 35 per cent magnesium. The solubility of  $\text{Al}_2\text{Mg}_3$  in Al has never been determined; it is approximately 10 per cent.

Schirmeister (see below) has investigated the rolling and mechanical properties of this series. Up to 6 per cent magnesium the alloys may be rolled hot and cold; beyond that they are too brittle.

Lane (320) has studied the effect of small amounts of magnesium in dioxidizing and hardening sand cast 99 per cent aluminium. Averages of his results are plotted in figure 16. It is interesting to note that the effect of the magnesium makes itself evident in stages.

Alloys of this series are lighter than aluminium and have attracted on that account much interest from those seeking strong light alloys. Under the name of magnalium, alloys of this series are used for casting purposes, and are described below. This series has never become commercially important for rolling alloys. Alloys having 30 per cent and more of magnesium take a high polish and are used for mirror metal.

## 4. ALUMINIUM-MANGANESE AND ALUMINIUM-MANGANESE-COPPER

This binary system has been studied by Hindrichs (405). A compound,  $\text{MnAl}_2$  (?) is formed, giving a eutectic with aluminium at 3 to 4 per cent manganese and 650 deg. C. It is insoluble in aluminium.

Schirmeister (see below) has contributed results of tests of light manganese-aluminium alloys.

Rosenhain and Lantsberry (466) have carried out some tests on light alloys of the manganese-copper-aluminium series. Their investigation concerns itself

FIG. 16.—EFFECT OF MAGNESIUM ON THE TENSILE PROPERTIES OF ALUMINIUM SAND CASTINGS (LANE)

primarily with the alloys rich in copper; only a few tests were made of the strength of the alloys at the aluminium end of the diagram. Table 9 shows the results of

tests of sand and chill castings of different compositions of alloys up to about 4 per cent of copper and 2 per cent of manganese. After making these tests the authors selected two alloys, Nos. 10 and 11, and tested these alloys both in the sand and chill cast condition and as rolled and drawn from ingots 3 in. in diameter. The results of these tests are shown in Table 10. Impact tests made with the Izod machine on rolled alloys showed that the No. 10 required 4.1 ft.-lb. and No. 11, 5.5 ft.-lb. of energy per unit of section in fracture.

The authors conclude that the results on rolled and drawn bars are disappointing and that the superiority found in alloy No. 11 in the form of chill casting was not maintained in the rolled condition. The results show that these alloys have very nearly the same physical properties as the copper-aluminum alloys which were investigated by Carpenter and Edwards.

Alternating stress tests carried out on  $\frac{3}{8}$ -in. diameter rolled bars of No. 10 and No. 11 alloy gave the following values for the ranges of maximum safe stress under which these alloys would bear an unlimited number of reversals:

Alloy No. 10..... 21,000 lb. per sq.in.

Alloy No. 11..... 19,700 lb. per sq.in.

The authors also carried out some corrosion experiments on chill castings of two alloys, the results of which are found in the table below.

| Alloy                                  | Loss of Weight, Lb. Per Month<br>(30 days) |
|----------------------------------------|--------------------------------------------|
| Chill Castings of                      |                                            |
| Pure aluminum.....                     | 0.000121                                   |
| Alloy No. 10 (1.9% Mn, 2.06% Cu).....  | 0.000275                                   |
| Alloy No. 11 (0.94% Mn, 2.89% Cu)..... | 0.000128                                   |

The specimens were machined from castings and immersed for 121 days. The resistance to corrosion in sea-water of the alloys is much superior to that of aluminium. These results are contrary to usual experience with relative corrosion resistance of aluminium and its light alloys (Seligman; discussion).

Tests of resistance to corrosion by sulphuric and nitric acids of alloys of from 1 to 10 per cent Mn showed that these alloys were less resistant to the attack of these acids than pure aluminium.

## 5. ALUMINIUM-NICKEL AND ALUMINIUM-NICKEL-COPPER

The constitution of this alloy series has been studied by Gwyer (409). A compound, NiAl, is formed which forms a eutectic with aluminium at 7 per cent nickel, and 630 deg. C. This compound is not soluble in aluminium. A thermal transformation occurs at 550 deg. C. in the alloys containing from 0 to 42 per cent nickel. Reed and Greaves (456, 458) give the results of some tests of these alloys.

The authors have made a study of the properties, microstructure, and corrosion of light aluminium alloys with nickel and copper.

Some preliminary tests of the working properties of such alloys were made. Strips 35 in. in length were rolled cold with the necessary annealings, if possible to a thickness of 0.10 in. and then without further annealing to a strip having a thickness of 0.02 in. Those alloys which were perfectly sound after this treatment and did not crack or break down are comprised within the following percentages:

| Copper | Nickel |
|--------|--------|
| 0.0    | 4.0    |
| 3.5    | 4.0    |
| 2.0    | 2.0    |

A portion of each  $\frac{3}{8}$ -in. diameter rod was turned down to  $\frac{1}{8}$ -in. diameter and drawn into wire. The diameter at which the drawing had to be abandoned serves as a measure of the relative ductility of the material. Alloys within the following compositions passed through a hole of 0.033 in. in diameter without cracking or hollow drawing:

| Alloy                                  | Loss of Weight, Lb. Per Month<br>(30 days) | Nickel | Copper |
|----------------------------------------|--------------------------------------------|--------|--------|
| Chill Castings of                      |                                            |        |        |
| Pure aluminum.....                     | 0.000121                                   | 0      | 0      |
| Alloy No. 10 (1.9% Mn, 2.06% Cu).....  | 0.000275                                   | 3      | 2      |
| Alloy No. 11 (0.94% Mn, 2.89% Cu)..... | 0.000128                                   | 1      | 4      |

TABLE XI—TENSILE PROPERTIES OF ALUMINIUM-COPPER-NICKEL ALLOYS (Read and Greaves, 456, 458)

| PHYSICAL PROPERTIES |                                           |                 |                                     |                                |                              |                            |                                        |                 |                                     |                                |                              |                            |                                     |                                |                              |                            |        |        |        |      |      |      |    |

(1) 21 x 18-in. ingot, chill cast, heated to 400 deg. C. rolled hot to 1 in. diameter

(2) The same annealed at 450 deg. C.

(3) The same as (1) cold drawn to  $\frac{1}{8}$  in. in 2 passes

Small blocks of metal,  $1\frac{1}{2} \times 1 \times 1\frac{1}{2}$  in., were forged down hot to a thickness of  $\frac{1}{2}$  in. after heating to 450 deg. C. Those compositions which remained perfectly sound under this treatment were comprised within the following:

| Nickel | Copper |
|--------|--------|
| 7.5    | 0.0    |
| 0.0    | 5.7    |
| 2.0    | 4.0    |
| 5.0    | 2.0    |

Tests of the alloys were made as chill cast and as rolled. The chill cast ingots were 1 in. in diameter. For the rolled alloys an ingot was chill cast,  $2\frac{1}{2}$  in. in diameter by 18 in. long, weighing about  $7\frac{1}{2}$  lb. This was rolled by the British Aluminum Company to 1-in. diameter rod at about 400 deg. C. A portion of the resulting rod was cold drawn in two passes to  $\frac{3}{4}$ -in. diameter rods. Some of the 1-in. diameter hot rolled rods were annealed. The results of these tests are shown in Fig. 17 and Table XI.

It will be noticed that although the ductility of the alloys of copper-nickel-aluminum in the chill cast and in the rolled state is high, these alloys do not show a very high tensile strength. The highest tensile strength in the series is that of a cold drawn rod containing 2.1 per cent of copper and 5.3 per cent of nickel; the tensile strength of this alloy in a cold drawn state is only 37,800 lb. per sq.in.

The authors made no study of the effect of heat treatment upon rolled alloys.

Tests of the effect of annealing and of quenching on chill cast alloys containing both copper and nickel showed that both annealing and quenching lowered the

FIG. 17.—TENSILE PROPERTIES OF ALUMINIUM CHILL CAST ALLOYS (READ AND GREAVES)

tensile strength slightly (from 1000 to 2000 lb. per sq.in.) with but slight increase (1 to 1.5 per cent) in elongation.

Alternating stress tests made on the Arnold machine

showed that the resistance to this test decreases with increase of both copper and nickel content.

The authors carried out corrosion tests both in sea- and in fresh-water on plates, both cold rolled and annealed,  $2 \times 1 \times 0.15$  in. Their results are given in Table 12. The results show that the alloys although inferior to pure aluminum in their resistance to corrosion are somewhat superior to other types of alloys in this respect; copper appears to accelerate corrosion more than nickel.

The authors also observed that the superiority shown by the nickel-aluminum alloys to ordinary corrosion in water was not maintained when dilute vinegar, oxalic acid, citric acid and tartaric acids were used.

The authors draw no general conclusion from their work but it is evident that the alloys of the compositions which they studied do not show a great enough strength to be considered as an alloy to be rolled into structural shapes. All the compositions were definitely inferior to duralumin.

On the other hand, the chill cast alloys look somewhat more promising and in view of the superior resistance to corrosion of the alloys of nickel and aluminium over those of copper and aluminium, may compete with the latter series in this form.

## 6. ALUMINIUM-SILICON

Fraenkel (420) has investigated the aluminium-silicon equilibrium. These metals form a simple eutectic series with the eutectic at 10 per cent (atomic) of silicon and at 580 deg. C. Silicon is not soluble in aluminium to the extent of more than approximately 0.5 per cent.

FIG. 18.—TENSILE PROPERTIES OF ALUMINIUM-ZINC SAND CAST ALLOYS (ROSENBAIN AND ARCHBUTT)

Schirmeister (see below) gives the results of some mechanical tests of aluminium-silicon alloys.

## 7. ALUMINIUM-ZINC

The constitution of this series of alloys has been studied by Lorenz and Plumbridge (436), Rosenbain (439), Shepherd (447) and others. Aluminium and zinc form a eutectiferous series, the eutectic lying at 95 per cent of zinc and 380 deg. C. A compound,  $Al_2Zn$ , is formed decomposing at 256 deg. C. Aluminium takes up approximately 40 to 20 per cent of zinc in solid solution, depending on the temperature.

The principal investigation of this alloy series is that of Rosenbain and Archbutt (438), who besides their study of the constitution of the alloy series carried out tensile, impact and alternating stress tests of cast and wrought alloys. The tensile properties were studied at

higher temperatures, and corrosion tests made on castings.

In Fig. 18 are shown the results of tensile tests of sand cast alloys of aluminium-zinc prepared by melting in an oil furnace, care being taken to keep the temperature below 800 deg. C.; the castings were 7 in. long by  $\frac{3}{8}$  in. in diameter. It is seen that the tensile strength of the alloys increases with the percentage of zinc. In Fig. 19 are shown the results of tensile tests

FIG. 19.—TENSILE PROPERTIES OF ALUMINIUM—ZINC CHILL CAST ALLOYS (ROSENBAIN AND ARCHBUTT)

of chill cast alloys poured into a chill mold 7 x  $\frac{3}{8}$  in. in diameter. It will be noted that the strength of such chill castings is slightly greater at all compositions than that of the sand castings; this is due primarily to the greater density of such castings.

The authors made some tests to determine whether the cast alloys of this series were subject to spontaneous disintegration. A certain number of sand cast specimens of zinc contents varying from 9 to 75 per cent were laid on one side when the alloys were originally made and tested. These were tested after an interval of fifteen months, . . . and it was found that there was no sign whatever or any disintegration, so if these alloys are subject to any aging process at all it must be of an extremely gradual character. It was found, however, that in every case there had been an increase of tensile strength, varying from 500 to 4000 lb. per sq. in., accompanied in some cases by decrease, in others by increase of elongation.

This agrees with practical experience with these alloys in that immediately after casting they are not readily machined, but "drag"; after aging for a few weeks a marked improvement in machinability occurs.

"Compression tests on both sand and chill castings showed that in general the compressive strength of these alloys is approximately proportional to their tensile strength, although the yield points in compression are also decidedly lower than the ultimate strength in tension."

In the discussion on this paper, Seligman (British Aluminium Co., Ltd.) states that the reason why composition above from 13 to 14 per cent of zinc had not hitherto been used for casting purposes was that it was the experience of the manufacturers that such alloys were sensitive to vibration and shock and hence not suitable for the motor industry.

Ingots were prepared of different compositions, 20 in. long and 3 in. in diameter. They were heated to approximately 400 deg. C. and hot rolled to  $1\frac{1}{8}$ ,  $\frac{3}{4}$  and  $\frac{1}{2}$  in. respectively. The 25 per cent zinc-aluminium alloy could fairly readily be rolled, but the 30 per cent alloy cracked considerably, even upon rolling it to  $1\frac{1}{8}$  in. in

diameter, so that 25 per cent may be looked upon as the maximum composition that can be rolled.

For some of the later series a rolling temperature of from 315 to 364 deg. C. was used with better results than at the higher temperatures. Some other experiments on the malleability of these alloys under the hammer at higher temperatures showed that the malleability increased with increase of temperature up to 400 deg. C., but that at 450 deg. C. the test specimen cracked, and at 500 deg. C. broke into coarse powder.

Samples of the  $1\frac{1}{8}$ -in. hot rolled bars were used for cold drawing experiments, the object aimed at being to reduce them by steps of  $\frac{1}{16}$  in. down to a diameter of  $\frac{1}{8}$  in. Compositions up to 15 per cent stood this cold drawing well. Above that the samples either drew hollow or broke.

The 15 and 20 per cent alloys were cast into slabs measuring  $13\frac{1}{2} \times 10\frac{1}{2} \times \frac{1}{2}$  in., heated to 400 deg. C., cooled to 300 deg. C., hot rolled to 0.13 in., annealed at 400 deg. C. and cold rolled to 0.7 in. The 15 per cent alloy behaved satisfactorily under this treatment. The 20 per cent alloy exhibited a small amount of cracking at the edge of the sheet, a defect which may have arisen from roughness of the original casting.

Fig. 20 shows the results of tests of hot rolled bars  $1\frac{1}{8}$  in. in diameter. These alloys exhibited a well-defined yield point accompanied by a sharp drop of the beam of the testing machine, similar to that found in the testing of mild steel. Similar curve series were obtained showing the results of tensile tests of hot rolled bars,  $\frac{3}{8}$  in. and  $\frac{1}{2}$  in. in diameter. The results of the former series are shown in Fig. 21. The curious fact is definitely ascertained that the alloys containing more than 15 per cent of zinc appear to deteriorate when a large amount of work is put upon them. It is seen that

FIG. 20.—TENSILE PROPERTIES OF ALUMINIUM—ZINC ALLOYS;  $1\frac{1}{8}$ -IN. HOT ROLLED BAR (ROSENBAIN AND ARCHBUTT)

although for compositions below 15 per cent of zinc the strength of the  $\frac{3}{8}$ -in. diameter rod is higher, as might be naturally expected, than that of the  $1\frac{1}{8}$ -in. diameter rod, above that percentage the reverse is true.

A study of the tensile strength of hot rolled and annealed bars shows that for compositions between 13 and 20 per cent the application of work upon the alloys appears to have beneficial effect, which is not entirely removed by annealing. The results on one series are shown in Fig. 21. In considering the strength of cold

drawn bars drawn to  $\frac{13}{16}$ -in. diameter from the hot rolled  $\frac{1}{2}$ -in. diameter rods, it is most remarkable that the ultimate strength of the cold drawn bars is very little higher than that of the original hot rolled bars from which they were drawn; it is noted that the alloys higher in zinc (above 15 per cent) show a lower ultimate strength in the cold drawn than in the hot rolled state.

Tests made on wire, 0.128 in. in diameter, as cold drawn, show that the strength of such wire is consider-

FIG. 21.—TENSILE PROPERTIES OF ALUMINIUM—ZINC ALLOYS (ROSENBAIN AND ARCHBUTT)

ably above that of any other form of the same material until a composition of 20 per cent of zinc is reached; thereafter the strength of the wire is less than that of the original  $\frac{1}{2}$ -in. hot rolled bars.

"We thus arrive at the very remarkable result that no amount of further work, whether applied to the metal when hot or cold, increases the tensile strength of the 25 per cent alloy beyond that which is attained in the form of  $\frac{1}{2}$ -in. hot rolled bars, the only marked effect of cold work being to bring about some reduction in the ductility of the alloy."

The tensile strengths of the two compositions rolled out into sheet 0.07 in. in thickness were very nearly the same as those obtained on bars, drawn with annealing as shown below:

Fifteen per cent alloy sheet, as rolled and tested longitudinally—tensile strength 47,000 lb. per sq.in.; elongation 1.5 per cent in 2 in.

Twenty per cent alloy sheet, similarly—tensile strength 50,500 lb. per sq.in.; elongation 0.5 per cent in 2 in.

After annealing at 400 deg. C., these two alloys showed 33,000 and 43,000 lb. per sq.in. tensile strength, and 24 and 10 per cent elongation, respectively.

Figs. 20 and 21 show the specific tenacity, the tensile strength divided by the density, of sand cast and hot rolled aluminium-zinc alloys and of hot rolled aluminium-copper alloys, the latter being taken from the data by Carpenter and Edwards. It will be noted that the aluminium-zinc alloy of 20 per cent shows a greater strength per unit mass than the highest strength alloy recorded by Carpenter and Edwards for the light aluminium-copper alloys.

Alternating stress tests carried out with alternations of direct stress on specimens cut from  $\frac{1}{2}$ -in. diameter hot rolled bars gave the following results:

| Per Cent Zinc | Maximum Safe Range of Stress, Lb. Per Sq. In. <sup>1</sup> |
|---------------|------------------------------------------------------------|
| 5             | 11,200                                                     |
| 9             | 15,000                                                     |
| 11            | 19,200                                                     |
| 17            | 22,400                                                     |
| 26            | 26,900                                                     |

<sup>1</sup> Giving about 1,000,000 reversals to rupture.

Impact tests carried out on the Izod machine gave the following results:

| Per Cent Zinc | Ft. Lb. Per Sq. In. Absorbed in Rupture |
|---------------|-----------------------------------------|
| 5             | 3.9                                     |
| 9             | 4.3                                     |
| 13            | 5.4                                     |
| 15            | 5.8                                     |
| 17            | 5.75                                    |
| 20            | 5.8                                     |
| 26            | 4.1                                     |

Tensile tests were carried out at higher temperature on several of the alloys. Some of the results are given in Table 13 below. Determinations made of the coefficient of thermal expansion between 0 and 18 deg. C.

TABLE XIII.—TENSILE PROPERTIES OF ZINC-ALUMINIUM ALLOYS IN FORM OF  $\frac{1}{2}$ -IN. ROLLED BARS AT HIGHER TEMPERATURES (Rosenbain & Archbutt, 438)

| 50                | 50,800                                | 40,100                           | 21                                 |
| 75                | 45,700                                | 34,400                           | 21                                 |
| 100               | 41,000                                | 33,200                           | 21                                 |
| 150               | 35,300                                | 30,200                           | 19                                 |
| 200               | 24,600                                | 21,800                           | 18                                 |

of these alloys in the form of  $\frac{13}{16}$ -in. diameter rolled bars yielded the following values:

| Per Cent Zinc                | Coefficient of Thermal Expansion |
|------------------------------|----------------------------------|
| 5                            | 0.000227                         |
| 15                           | 0.000231                         |
| 20 ( $\frac{1}{2}$ -in. bar) | 0.000234                         |

Sand and chill castings  $3 \times 4 \times \frac{3}{8}$  in. were machined and exposed for 521 days to the action of sea-water. The losses in weight were measured and are given in the table below:

| Per Cent Zinc | Corrosion of Zinc-Aluminium Alloy Castings |          |  | Month Castings in Sand |
|---------------|--------------------------------------------|----------|--|------------------------|
|               | Loss of Weight in Lb. Per Sq. In.          | Per Cent |  |                        |
| 5             | 0.0012                                     |          |  | 0.0054                 |
| 9             | 0.0017                                     |          |  | 0.0092                 |
| 15            | 0.0018                                     |          |  | 0.0062                 |
|               | 0.0023                                     |          |  | 0.0145                 |

The sand castings were thus superior to the chill castings in this respect.

In the appendix to this report the authors describe an alloy consisting of 25 per cent of zinc, 3 per cent of copper and 62 per cent of aluminium. This alloy shows a tensile strength of about 41,000 lb. and 45,000 lb. in the sand and chill cast condition, respectively. The rolling of this alloy presents considerable difficulty but if careful temperature control is exercised it can be hot rolled. This alloy gave a tensile strength, in the form of  $\frac{1}{2}$ -in. hot rolled bar, of 71,000 lb. per sq.in., a yield point of 61,000 lb. per sq.in. and an elongation in 1 in. of 21 per cent. The specific gravity of this alloy is 3.29.

Summarizing the work of these investigators on the physical properties at ordinary temperatures, the following points may be noted:

1. It has been found possible to roll out into bars and even to draw into wire an alloy containing as much as 26 per cent of zinc. This alloy attains its maximum tensile strength when in the condition of hot rolled bars  $\frac{1}{2}$  in. in diameter, the maximum strength being 62,000 lb. per sq.in. This alloy has a density of 3.24 when hot rolled.

2. Further rolling down of this alloy does not improve, but impairs, the tensile properties of the material.

3. Both the binary and ternary alloys referred to differ from the majority of non-ferrous alloys in the fact that in the rolled condition they exhibit a definite and well-marked yield point similar to that of mild steel.

4. A great defect of this group of alloys is their great sensitiveness to rise of temperature in relation to their tensile strength. Thus the alloy containing 25 per cent of zinc loses 33 per cent of its tensile strength (at 20 deg. C.) when the temperature is raised to 100 deg. C. The highest tensile strength of the cast alloys determined was 42,000 lb. per sq.in. for an alloy containing 50 per cent of zinc; the highest for the wrought alloys was that of the 1½-in. hot rolled bars of 26 per cent zinc content and having a tensile strength of 62,000 lb. per sq.in., a yield point of 56,000 lb. per sq.in. and an elongation of 16.5 per cent in 3 in.

5. Tests made of the resistance of these alloys to alternation of direct stress gave a series of results for the safe range of alternating stresses which lies considerably below that of the static elastic limits. The 25 per cent alloy showed a safe range of 27,000 lb. per sq.in. Single-blow impact tests made on the Izod machine showed that the work absorbed by fracture reaches a maximum for a zinc content lying between 15 and 20 per cent; this, for an alloy containing 15 per cent of zinc, is 5.8 ft.lb. Under Prof. Arnold's alternate bending tests the endurance of the alloys falls rapidly with the increase of zinc content.

## Organizing Research Work on a National Scale

THE proposal has been many times made that the work of scientific and technical research, now carried on independently by a multitude of institutions and individuals, should be organized on a national scale. Such an organization, could it be effected, would make unnecessary a vast amount of needless duplication of work. It would further be possible, by concentrating research workers on a particular task, to make much more rapid progress; and by giving the results of successful research greater prestige and standing, it would be possible to secure the adoption of new developments in practical work to a much greater extent than at present. The magnitude of the task of controlling and coördinating the research work of the entire country is such, however, that no serious attempt to do this has ever been undertaken until the war brought the need and opportunity home.

Two years ago President Wilson accepted an offer by the National Academy of Sciences to undertake the organization of the scientific resources and research facilities of the country. The National Research Council was organized, in accordance with this offer, a year in advance of this country's actual declaration of war, and it was officially recognized by the Council of National Defense and arranged to serve during the war as a department of that body early in 1917.

While the National Academy of Sciences, from which the National Research Council sprung, deals only with so-called "pure" science, it was recognized from the outset that the business of the Council was to pro-

mote research which aimed at definite, practical results.

The Executive Order of President Wilson, issued on May 11, recognized the work which has already been accomplished by the Council and ordered the coöperation with it of the scientific and technical branches of the Government. The practical nature of the Council's work was attested at the outset by the fact that its first financial support came from the Engineering Foundation; and is attested now by the fact that Governmental appropriations to the amount of \$270,000 have been made to finance special branches.

The work accomplished by the Council and its organization and plans were the subject of an address by the Council's Chairman, Dr. George Ellery Hale, delivered on May 28 before a joint meeting of the National Engineering Societies in New York City.

As much of the research directed by the Council relates to apparatus useful in the war, detailed statements concerning such work cannot be made public. It can be said, however, that among the problems with which the Council is dealing are processes for making nitrates, the manufacture of optical glass, materials conveniently located for highway construction along the Atlantic coast, methods of combating the submarine, the development of body armor, range finders, location of enemy heavy artillery by sound, psychological tests of recruits. These are but samples at random of the numerous fields in which committees of the Council are at work.

Dr. Hale, in his address, emphasized that the Council recognizes the great value of individual initiative and direction. It will aim to coöperate with and aid the individual worker and not to supersede him. A statement of Dr. Hale's which won hearty applause from his audience was the following:

"It should be said here, once for all, that the policy of the National Research Council has been from the outset invariably to recommend the immediate development and utilization for military and naval purposes of the best devices or methods known at the time, with the understanding that research for the purposes of improving such devices should not retard production demanded to meet pressing military needs."

In the special work of coöperating with existing research agencies, a census has been made under direction of Dr. S. W. Stratton, Chief of the Bureau of Standards, of the research workers and facilities in the universities, manufacturing plants, Federal Government bureaus, commercial testing laboratories, etc., throughout the United States. Another committee, of which Dr. John C. Merriam of the University of California is Chairman, has secured the organization of local research committees in 72 universities and colleges to coöperate with the National Council and in many cases with local industries.

There has also been organized with the approval and coöperation of the Secretaries of War and the Navy, a committee to interchange technical information and the results of research work with the authorities of Great Britain and France. This committee has offices in Paris, London and Washington. Dr. W. F. Durand represents the committee in Paris and Dr. H. A. Bumstead in London. The Council of National Defense has provided funds to the amount of \$38,400 for this committee's work for the current year.

## Synopsis of Recent Chemical and Metallurgical Literature

**A New Illuminator.**—The travel of the source of light in an ordinary arc, its flicker, poor color distribution and need of constant adjustment when used as a mode of illumination for microscopic, photographic, or projection work may apparently be obviated by the substitution of gas-filled lamps, according to a description published in *Electrical World* by R. P. BURROWS and J. T. CALDWELL, of the Engineering Department of the National Lamp Works of the General Electric Co. The

FIG. 1.—RELATIVE POSITIONS OF GAS-FILLED LAMP, MIRROR AND CONDENSER FOR PROJECTION PURPOSES

inherent limitation of the filament lamp, that is, the relatively low intrinsic brilliancy of the source has been limited by the life of the filament—the higher the temperature the shorter the life and the greater the candle power emitted per unit area of filament; and second, limited by the diameter of the filament—in general the greater the diameter of the filament the higher the operating temperature for the same life. With gas-filled lamps the brilliancy is limited to about one-fourth that of a good direct-current arc, so the success with which

FIG. 2.—IMAGE OF FILAMENT FALLS BETWEEN COILS GIVING SOLID PLANE OF LIGHT

the light is projected depends upon the utilization of the light. The optical properties of the condensing lens evidently limits the effective size of the light source available. For this reason the "monoplane" filament has been developed, and is so arranged that all of the coils are in one plane. This construction allows most of the filament to come within the focus area of the lens system. The light from the rear portion of the filament is gathered and redirected as useful light by a spherical mirror (see Fig. 1). As shown in Fig. 2 images from the filament can be made to fall at points

between the filament coils, which gives a solid plane of light as photographed in Fig. 3. It may readily be seen that if a large bulb were to be used to inclose the filament, advantage could not be taken of the short-focus condensing lens (a prismatic lens of the Fresnel type with a 76-deg. solid angle is used); consequently it is necessary to use a bulb of as small a diameter as is practically possible. This bulb is tubular and of such length that the fine particles given off by the filament are carried upward by the hot gas and deposited on a portion of the bulb well out of the zone of useful light.

In obtaining concentration of filament it is necessary to get as high a wattage and filament brilliancy as possible for the size of light source previously determined. This can be most easily accomplished by the use of a large diameter wire, or, in other words, through the

FIG. 3.—FILAMENT ALONE AND WITH IMAGE BETWEEN COILS

use of a high-current, low-voltage lamp. This is objectionable from one standpoint, in that it cannot be used on regular lighting circuits.

A transformer has been developed which can be used on 110- to 120-volt and 220-volt alternating-current circuits. This transformer includes a variable resistance, or a reactance, in the primary circuit to take care of the variations in line voltage, thus enabling the operator to maintain the normal current on the lamp. An ammeter is placed in the secondary circuit of the transformer, and a four-point starting switch is included in some equipments. This switch eliminates the possibility of a rush of current through the cold lamp when the current is first applied, for the connections are such that the current is gradually increased as the switch is thrown in.

**Strength of Oxyacetylene Welds.**—In Bulletin 98, University of Illinois, Prof. H. F. MOORE describes the results of tests performed on oxyacetylene welded joints in mild steel plates. The joints were made by skilled workmen, and should therefore be regarded as better than the joints made in ordinary welding shops. The static tension tests showed a joint efficiency of 100 per cent in plates one-half inch thick or less, decreasing with thicker plates. The joints were strengthened by working after welding, but were weakened by annealing at 800 deg. C. The efficiency of the material is always less than the efficiency of the joint, indicating the necessity of building up the weld to a thickness greater than that of the plate. Alternating stress tests follow in a general way the results given by static testing. Under impact the joints are decidedly weaker than the original material; for points welded with no subsequent treatment the strength under impact is about half that of the plate. If the weld is worked while hot the impact resisting qualities are slightly improved, while annealing at 800 deg. C. has little effect.

**Gases, Oxides and Blowholes in Admiralty Bronze.**—Prof. H. C. H. CARPENTER and Miss C. F. ELAM have experimented in the foundry of Mr. J. Dewrance, originator of this alloy, and presented their findings before the March, 1918, meeting of the Institute of Metals (British). They cast 3½-inch square ingots, 6 inches long at various temperatures determined by a thermocouple in the crucible at the time of pouring. For examination, the ingots were cut in half and machined in a special way to obviate the use of etching reagents, which would tend to increase the size of blowholes and other physical defects. A cut of 0.01 inch depth is taken with a feed of 0.01 inch with a very sharp square-pointed tool 0.01 inch wide.

They find that unsoundness was always associated with high temperature of pouring, irrespective of the kind of copper used—sand cast ingots showed a few large holes, while chill casting developed a multitude of minute ones. By alternately pouring from about 1400 deg. C. and allowing the metal to cool in the crucible to 1225 deg., the same metal is rendered alternately unsound and sound. The actual casting operation, therefore, provided the temperature is sufficiently high, is the deciding factor in producing sound ingots, and KARR and RAWDON's conclusions in *Technologic Papers* of the Bureau of Standards, No. 59, that the best results could be obtained by pouring within the range of 1120 and 1270 deg. C. is confirmed in general. Melting and casting *in vacuo* is uncommercial, and would not eliminate all the gas introduced with the cold metal. Holding the melting furnace at 1270 deg. is impracticable owing to the reduction in the speed of melting. The action of scavengers and deoxidizers is still uncertain. The best way is to measure the temperature of each crucible before pouring by proper optical pyrometers—practice

purities, much of their quantity being skimmed off the melt before pouring. It is very difficult to distinguish between tin and zinc oxides. Ferric chloride and hydrochloric acid will dissolve the zinc oxide, but will not attack the other.

The authors conducted many experiments to determine the composition of the gases filling the blowholes (evidently reducing in nature by the brightness of the cavity walls). Their results were somewhat variable. The small volume of gases obtainable was given off very

FIG. 3.—OXIDE INCLUSION, UNETCHED; x 500

FIG. 4.—OXIDE FILMS, UNETCHED; x 500

slowly, was of complex nature approximating the furnace atmosphere, and varied in composition depending upon the method of collection. If the gas is removed as quickly as it comes off, it has a smaller volume, its chief characteristics being a large percentage of sulphur dioxide and hydrogen sulphide and a small percentage of hydrogen; if, on the other hand the gas is removed slowly or heated for a long time in contact with the hot tube and metal, the volume is larger than in the former case. There is then a large percentage of hydrogen, and the sulphur dioxide and hydrogen sulphide are either low or entirely absent. The zinc is largely responsible for this change, as there is much less difference in the gases collected in the two ways from pure furnace-refined copper. Zinc may act in this manner by lowering the solubility of the gases in the alloy, or by volatilizing *in vacuo*, reacting with the sulphur forming zinc sulphide which forthwith condenses on the inside of the tube. There is no outstanding difference between the gases collected from sound and unsound castings which would account for the presence or absence of the blowholes. It cannot be concluded from their experiments that there is any gas present in the metal poured too hot that is not in sound metal, nor does it appear that there is a larger volume of any one gas or gases present in the one than in the other. Experiment showed that there is a drop of about 100 deg. C. in the temperature of the metal in passing from the crucible to the mold. The explanation appearing most probable is based on the fact which they have established that this mixture of gases can exist in more than one form, each possessing its characteristic volume and composition. The sudden change in temperature of the alloy on pouring is sufficient to cause a reaction or a decomposition of certain of the gases, with the formation of another gas mixture with a relatively large volume which is insoluble in the alloy.

FIG. 1.—OXIDE INCLUSION, CONSISTING OF TWO OXIDES, UNETCHED; x 500

FIG. 2.—OXIDE INCLUSION, UNETCHED; x 500

of this method should be easy in comparison with that of progressive steel makers who try to control the temperature of casting to within 20 deg. at 1600 deg. C.

Figs. 1 to 4 show various inclusions of oxides found on microscopic examination. These are often associated with the delta copper-tin constituent—the light portion of Fig. 2. The rhombohedral inclusions of Fig. 3 occurred in metal often remelted and containing little or no zinc. One would expect the copper oxide formed in melting to be reduced by zinc and tin when they are added; the oxides of the two latter being insoluble, collect and liquitate as mechanical im-

## Recent Chemical and Metallurgical Patents

**Ammonia by Hydrogenation of Nitrogen.**—The processes for the production of synthetic ammonia by the hydration of aluminium nitride and calcium cyanamide are well known commercially. MR. CARLETON ELLIS, of Montclair, N. J. (assignee, C. S. Lutkins, Rye, N. Y.), has patented a more direct process passing a mixture of nitrogen and hydrogen at high pressures and temperatures (40 atm., 500 deg. C.) in volume proportions of one to three over catalytic materials of the type of nickel-cobalt carbides whereupon a chemical reaction takes place producing synthetic ammonia. (July 23, 1918; 1,273,772.)

**Process of Producing Cyanamides.**—VICTOR THRANE, of Christiania, Norway, patents the use of the Hoffmann Ring furnace, together with the sifting of inert materials over the furnace conveyors in order to prevent the fusion of the carbides thereon during the nitridding of the calcium carbide. The conveyor moves the carbide charge countercurrent to the flow of nitrogen and is so speeded that time for completing the reaction is allowed in approaching and passing through the fired zone. The use of the inert intermediate material expedites the discharge of the conveyor. In the many installations of these furnaces in the German pottery works, sand has been universally used to protect the metal mechanical parts, it having the property of flowing readily when hot. (July 23, 1918; 1,273,690.)

**Production of Nitrogen.**—The process of removing oxygen from air by combustion with hydrogen in a gas engine and utilizing the force of the reaction in generating electromotive force for the electrolysis of water to maintain a continuous supply of hydrogen has been patented by MR. CARLO ANDREUCCI, of Rome, Italy. He has successfully practiced this process by bringing about by means of an electric spark the explosion of successive charges each of substantially 1000 liters of air (containing 209 liters of oxygen) with 418 liters of hydrogen, in the combustion cylinder of an internal combustion gas engine provided with an electric spark plug. The proportions given may be determined or regulated by operation of the throttling inlet valves, one for air and the other for hydrogen. About 336 grams of water and 778.3 liters of nitrogen mixed with oxides of carbon, argon, etc., are obtained per 1000 liters of air. (July 9, 1918; 1,272,181.)

**Depolarization by Sulphur Dioxide.**—F. E. STUETZ, of London, England, notes that it is undesirable to utilize the ferrous salts contained in solutions from leaching copper ores as a depolarizer when electrolyzing them, because the reaction,

is reversible, the ferric sulphate formed corroding the cathode copper, thus lowering the ampere efficiency. Using  $\text{SO}_2$  as a depolarizer prevents this effect, requires a lower cell voltage, and generates sulphuric acid. He therefore specifies the use of solutions properly reduced, containing little or no ferric iron, and saturated with

$\text{SO}_2$ . Proper cell conditions require constant circulation, a low current density (13 amps. per square foot) and a temperature of 49 to 53 deg. C. Liquid sulphur dioxide, readily made from smelter gases, is gasified, and introduced to the electrolytic tanks under a pressure of two to four atmospheres with a sufficient quantity of steam to maintain the temperature of the electrolyte in the required range. These gases enter through a grid of perforated lead pipes laid on the floor of the tanks, and placed in such a manner that a stream of bubbles impinges on both sides of each anode. This delivers the depolarizing agent to the exact place where it is needed, and maintains correct agitation. The steam effectually prevents the formation of crystalline growths tending to plug the small openings. The overflow from the electrolytic tanks is thus saturated with  $\text{SO}_2$ , which, if sufficiently long time is given in the leaching tanks, will reduce any ferric salts formed during that part of the cycle. (1,260,830; Mar. 26, 1918.)

**Electrode Construction.**—JAMES B. HERRESHOFF, JR., of Richmond Hill, New York, notes that the circulation of the electrolyte tends to carry small particles of impurities from the copper anode over to the cathode, where they lodge and thus contaminate the resulting deposit. It has been proposed to hang bi-polar electrodes

FIG. 1.

at an inclination, so that the cathode side is inclined downward, thus minimizing the tendency of any wandering slime particle to adhere. The inclination has ordinarily been effected by resting the lower end of the electrode against cross bars, which offer obstruction to the free settlement of slime, causing an accumulation of such material sufficient to short circuit portions of the cell. The inventor proposes to hang the electrodes freely in the solution at a proper and parallel inclination by casting an offset ear to the top, as shown in Fig. 1. (1,262,045; Apr. 9, 1918.)

## A Permeameter for General Magnetic Analysis

BY FRANK P. FAHY

THE writer has described<sup>1</sup> a permeameter for general magnetic testing in the use of which the difficulties formerly encountered in accurately and rapidly determining the magnetic properties of materials have been largely overcome. This apparatus calls for but one compensating adjustment and is so adapted that it may be used to simultaneously compare the properties of two specimens, one of which partakes of the character of a standard, or to measure the properties of a single specimen. The extended use of this permeameter in investigative work has disclosed that where a simultaneous comparative measurement is not required a great gain in simplicity of construction and ease of manipulation is possible without departing from the principle of operation or sacrificing accuracy. The new permeameter has no compensating adjustment and calls for no previous experience in magnetic testing on the part of the user.

FIG. 1.—SIMPLEX PERMEAMETER

Fig. 1 shows the new permeameter in standard form as arranged to take specimens from ten inches in length upward.

### THE MAGNETIC CIRCUITS

In Figs. 2 and 3 are shown the permeameter in plan and elevation. *A* represents the base of the apparatus upon which is mounted a magnetic core of U-shape, consisting of a yoke portion *B* and core arms *C* and *C'*. In the operation of the instrument the polar faces of these core arms are bridged by the material under test. The core is mounted upon supporting members *a* of non-magnetic material which are secured to the base *A*, the core arms being fastened to *a* by bracket members *a'* and core arm extensions *a''*. The core arm extensions *a''*, which are of magnetic material, are attached respectively to the outer portions of the core arms *C* and *C'* and to the supporting members *a* and bring about magnetic contact with the edge portion of the test specimen when the latter is of solid rectangular or lamellar sheet form.

*I* and *I'* are magnetic contact shoes to the lower ends of which are attached supporting blocks of non-magnetic material *a'* which engage with slots cut in the exten-

sions *a''* and serve to permit movement of *I* and *I'* toward and away from the pole faces of the core arms *C* and *C'*. The purpose of the supporting blocks *a'* is to retain the contact shoes *I* and *I'* at a definite distance from the extensions *a''* and to prevent magnetic

FIG. 2.—PERMEAMETER IN PLAN

contact therewith. Clamp supports *a'* of non-magnetic material are secured to the base *A* adjacent to the polar faces of the core arms *C* and *C'* and are provided with clamping screws *D*.

Upon the yoke portion *B* of the magnetic core is located a magnetizing coil *F*. A test coil *T*, within which the specimen under test is inserted, is situated at the ends of the core arms *C* and *C'*. A second test coil *H*, which is wound upon a solid non-magnetic core *K*, is affixed between the upper ends of the contact shoes

FIG. 3.—PERMEAMETER IN ELEVATION

*I* and *I'*. Fig. 4 shows diagrammatically the flux path within the core due to the magnetomotive force generated by current in the coil *F*. In practice this current is usually supplied by a storage battery. The magnetic field due to the current has the direction indicated by the arrows, or the reverse, according to the direction of flow of the current in the coil *F*.

### ELECTRICAL CONNECTIONS

Fig. 4 also shows diagrammatically the electrical connections of the permeameter. The magnetizing coil is connected to the terminals marked *F*, the test coil *T*

<sup>1</sup>Fahy, "A Permeameter for Magnetic-Mechanical Testing," *Electrical World*, Vol. 63, p. 315, 1917. See also "An Experimental Study of the Fahy Permeameter," *Scientific Paper No. 306* of the U. S. Bureau of Standards.

to the terminals marked *T* and the test coil *H* to the terminals marked *H*. The terminals *F* are connected, externally to the instrument, to a source of electromotive force *P* in series with an ammeter *O*, a controlling rheostat *RF* and a reversing switch *L*. Interposed be-

FIG. 4.—PLAN OF CIRCUITS

tween two of the points of switch *L*, as shown, is a second switch *L'* which bridges a rheostat *RF*. The terminals *T* and *H* are connected through controlling resistances *RT* and *RH* respectively to a multipoint switch *L'* so that each of these circuits may at will be connected to an indicating instrument *Q*.

This indicating instrument *Q* is a special form of galvanometer of the D'Arsonval type which is calibrated by a mutual inductance, not shown in Fig. 4. When the galvanometer is adjusted in accordance with the constants of the coils *T* and *H*, which is brought about by manipulation of the resistances *RT* and *RH* respectively, its reading indicates directly the magnetic effects operating upon the particular circuit to which it is connected.

#### BASIS OF OPERATION

In the use of the permeameter a test specimen *X* is inserted within the coil *T* and clamped in place by means of the screws *D*. The test specimen should preferably be long enough to span the outer extremities of the pole faces, and may be as much longer as desired. Comparative data may however be obtained with lengths which do not actually bridge the pole faces. The screws *D* engage with the magnetic contact shoes *I* and *I'* so that, as shown diagrammatically in Fig. 4, one face of the test material *X* makes contact at each end with a polar face of the core arms *C* and *C'*, while the opposite face makes contact with *I* or *I'*. By reason of the non-magnetic supporting blocks *a*, *I* and *I'* make magnetic contact solely with the material under test and not with any portion of the magnetic core.

The magnetic induction in the test material *X* is determined in the usual manner from the magnitude of the impulsive throw of the galvanometer which occurs when the latter is connected to the test coil *T* and the direction of flow or magnitude of the current in the magnetizing coil is changed. That is, a quantity of electricity flows through the galvanometer which corresponds in magnitude to the change in induction in the test material. When the galvanometer is connected to the coil *H* and the current in the magnetizing coil is changed in any manner, the impulsive throw of the galvanometer indicates the change in induction in the air space encircled by the coil winding *H*. This change

in induction corresponds to the change in magnetic potential existing between the ends of the test material. The average magnetic potential drop per unit length of the winding *H* is equal to the average magnetizing force to which the body *X* is subjected. Observation therefore of the throws of the galvanometer when the latter is connected in sequence to the coils *T* and *H* and the same change in current in the magnetizing coil is gone through indicates the induction and the corresponding magnetizing force.

The use of the shoes *I* and *I'*, which are of low reluctance, removes the necessity of having the ends of the coil *H* immediately in contact with the test material, which would seriously limit the practical utility of this method of measuring magnetizing force. Since the shoes are in magnetic contact with the material under test only, the magnetic potential measured is actually that operative on the specimen. Faulty contact between the test material and the magnetic core, which would cause excessive magnetomotive force drop at the polar contact faces and result in serious error in measurement if the magnetizing force were calculated from the ampere turns, knowing the constants of the magnetizing coil, which is a common method, has no appreciable effect on accuracy in the method here described. Such faulty contact may be due to the test material not being straight or having irregular or scaly surfaces. The compensating adjustments required in most permeameters are designed in large part to overcome such conditions by supplying additional magnetomotive force to offset the losses at the contact faces.

#### MANIPULATION

The test material is inserted within the coil *T* and the clamps *D* screwed up so that the material makes reasonably good contact with the polar faces of the core

FIG. 5.—NORMAL INDUCTION CURVE

arms and with the contact shoes. The material may be in the form of a very long bar and the test confined to any region along its length.

The galvanometer is calibrated by means of a mutual inductance, and the resistances *RT* and *RH* adjusted so that when successively connected to the coils *T* and *H* in the course of a test, the readings will indicate flux density. The flux density observed when the coil *T*

is connected to the galvanometer is subject to a slight correction to obtain the actual density in the material under examination. This correction is the result of the coil  $T$ , which must necessarily be somewhat larger in cross-sectional area than the test material, encircling more flux than threads the material alone. The flux density threading the coil  $H$  indicates directly the magnetizing force.

#### DETERMINATION OF NORMAL INDUCTION

The coil  $F$  is energized and the material under test demagnetized by repeated reversals of a successively decreasing magnetizing current. During these reversals and throughout the normal induction test, the switch  $L'$  is closed so that whether switch  $L$  be closed to the right or left the same current flows through coil  $F$ . The demagnetizing operation is for the purpose of freeing the material from the effects of any previous magnetization and it is sufficient for this purpose to start the demagnetization from a current value which carries the induction beyond the point of maximum permeability, as  $A$ , Fig. 5. After reducing the induction to practically zero, the magnetizing current is increased to the value which will give the lowest induction desired for the test data. This current is then reversed several times to bring the material into a magnetically cyclic state.

To read the induction, the coil  $T$  is connected to the galvanometer by means of the switch  $L'$  and the impulsive throw noted when the current in the magnetizing coil is reversed in direction by means of the switch  $L$ . To read the corresponding magnetizing force the galvanometer is connected to the coil  $H$  and the throw noted when switch  $L$  is again reversed. Successive readings of induction and the magnetizing forces corresponding thereto may be made by increasing the current in  $F$ , by steps, up to the point of maximum induction desired. No further demagnetizing is required for values of induction higher than the initial one.

#### DETERMINATION OF HYSTERESIS

Hysteresis determinations may be made from any value of flux density reached by the material under test. As indicated above, the hysteresis, for any given material, depends upon this maximum value of flux density. In the standard tests of materials which enter into electrical apparatus where we are directly concerned with the magnetic quality of the material, this induction is usually specified as 10,000 in the case of sheet steel, and for permanent magnet material as that induction which is reached under a magnetizing force of 200. In the investigation of materials where information as to their mechanical characteristics is sought, the maximum induction employed is that corresponding to practical saturation of the material.

In determining hysteresis, the switch  $L'$  is closed and the current in coil  $F$  increased to give the proper maximum induction. Switch  $L$  is then reversed several times, being finally thrown to the right, Fig. 4. The induction is then represented by the point  $C$ , Fig. 5. If switch  $L'$  is then opened, the rheostat  $R'F$  is then interposed in the magnetizing coil circuit, and both the induction and magnetizing force fall to the values represented by, say, the point  $D$ , Fig. 5. If the gal-

vanometer is successively connected to the coils  $T$  and  $H$  while this operation is gone through, the throws of the former will indicate the changes of induction and magnetizing force resulting. Subtraction of the values represented by these changes from the values represented by the point  $C$  will establish the point  $D$ .

Except where the material under test is extremely soft, or in other words of high permeability, the determination of the point  $E$  is made, having closed switch  $L'$ , come back to the point of maximum induction and reversed several times, by opening switch  $L$  and observing the changes in induction threading the coils  $T$  and  $H$

FIG. 6.—CONTROL BOX

as above. Opening the switch  $L$  reduces the magnetizing force to practically zero. However, the test material is still subject to a very small magnetizing force, which finds its source in the residual induction of the soft iron core of the permeameter. The amount of this magnetizing force is negligible in the testing of magnet steels and tools, but where it is necessary to take it into account establishing the point  $E$  requires the application of a small magnetomotive force in the reversed direction. The procedure is then the same as that for establishing the point  $F$ , described below, the only difference being in the amount of reversed magnetizing force applied.

To establish the point  $F$ , proceed as before, magnetizing the material to the point  $C$ , reversing switch  $L$  several times and finally closing it to the left, Fig. 4. Then having opened switch  $L'$ , throw switch  $L$  to the right. This reduces the magnetizing force from the value represented by the point  $C$  to a lower value in the reverse direction. To reduce the induction to zero, that is to establish the point  $G$ , start again from the maximum induction, adjusting rheostat  $R'F$  until the change of induction indicates that the induction has finally been reduced to zero.

In general, the determination of hysteresis in practice goes only as far as the determination of the points  $E$  and  $G$ . The ordinate  $OE$ , Fig. 5, represents the residual induction, or that induction which persists under zero magnetizing force after previous magnetization. The abscissa  $OG$  represents the coercive force, or that reversed magnetizing force which is required to reduce the residual induction to zero. These values, residual induction, designated by  $B_r$ , and coercive force, designated by  $H_c$  are the two important properties with which we are concerned in the examination of steels intended

for use as permanent magnet material. These quantities are of equal importance in the testing of materials where it is desired to interpret the magnetic data in terms of structural stability.

A control box, Fig. 6, has been designed for use in connection with this permeameter which contains in compact form the switching apparatus shown diagrammatically in Fig. 5, together with the mutual inductance for calibrating the galvanometer and the adjusting resistances.

The permeameter shown in Figs. 2 and 3 is especially adapted to the measurement of the properties of materials where it is convenient to prepare samples for test. For material which is round in section special bushings may be used to insure reasonably good contact at the polar faces. The instrument may also be used in the testing of diversely shaped tools, but with some special shapes a modification of the design is called for. The control equipment external to the permeameter proper is suitable for use with any modification of the instrument which is necessary by reason of special conditions or requirements.

The test procedure outlined above under "Manipulation" is seldom gone through in its entirety and only when all of the properties of the material under examination are to be determined, as an investigative work. In routine examination the test may be confined to the determination of the induction under a given magnetizing force, or the determination of the residual induction or coercive force, or both. It will frequently be found that but a single criterion is necessary to establish the nature of the material. When either permeability or hysteresis tests are made at reasonably high values of induction, which is almost always the case, there is no necessity of initially demagnetizing the test material.

76 Church St.,  
New York City.

### Automatic Blow-Case Valve

**A**N automatic device consisting of a compound liquid check valve and air line control employed for air blowing in acid montejus has been developed by the Monarch Manufacturing Works, Inc., 3128 Emery Street, Philadelphia, Pa. Fig. 1 shows the device, which consists of two flange-like parts. The heavy dotted line indicates the bases of the ribs, the intervals between which form parts for the flow of the incharging liquid around the check and air valves. The valves sit loosely on the seat formed by the ribs. Through the lower ribs, air ports are bored.

The acid flows from the storage tank, tank car etc. through the combination check valve and air device, into the monteju. As the blow case fills with liquid, the volume occupied by the air contained becomes smaller with accompanying compression. When this counter air pressure has become equal to the liquid head, a surging escape of air takes place, which unseats the air valve and allows an influx of compressed air through the rib air ports. This pressure is sufficient to seat the valve tightly against the upper inlet *s*, shutting off the inflow of liquid and discharging the acid from the base through the open discharge line. When the charge has been blown out, the air escapes so rapidly that the fluid head pushes the valves into the lower seats, stop-

liquid. This is made possible because the inverted-cup-shaped check does not rest on the air port stopper, thus pinging the discharge of compressed air and starting a recharge of acid.

A feature of this device is the operation of the valves, which are worked in counter-current to the inflowing

FIG. 1.—BLOW-CASE VALVE

allowing freedom for the easy upward movement of this part when the surging effect takes place. The manufacturers make this device in several sizes using all the usual materials excepting stoneware.

### All in Readiness for Chemical Exposition

More than 350 exhibitors have signed contracts to date for space at the Fourth National Exposition of Chemical Industries to be held in Grand Central Palace the week of September 23-30. This means that all of the floor space on the three available exposition floors of the building will be filled to capacity with the most interesting and varied displays relating to the chemical industry and its thousands of ramifications. When the public stops to consider that the wonderful drive now being made on the Western front is due in a large measure to the advances made in chemistry in this country since the beginning of the war, and that our chemical processes varying from munitions and poison gas to alloy steel are, like American fighters, superior to the German product, the importance of a great clearing house for the brains of this industry is at once apparent. That, in effect, is what the huge exposition is—a great get-together which affords the master minds an opportunity to meet in one place and exchange ideas in personal interview in a way that eliminates thousands of miles of railroad travel.

The fact that the United States Government is about to take over Grand Central Palace and convert it into a base hospital positively will not interfere with the holding of this exposition, which will terminate on September 30. In fact it is said that high officials of the Government considered this exposition such an important one that they would be loathe to interfere with its successful presentation. Arrangements have been made to remove the displays at the close of the exposition in ample time to suit the Government. The latest information regarding the building is that it will be remodeled to accommodate 3000 patients and will be ready December 1. The lease is for the period of the war and three months after.

## Book Reviews

**JAMES WOODHOUSE.** By Provost *Edgar Fahs Smith*. 299 pages. Price \$1.50. Philadelphia: The John C. Winston Company.

The chemical activities of James Woodhouse are of interest to all chemists, whether they have a taste for the history of the science and its literature or desire to confine their attention to bare practicalities. Dr. Smith has expended great efforts to convey an insight into the scientific character of this pioneer American chemical genius. His laboratory at the University of Pennsylvania was the forge where the weapons were wrought which conquered the phlogiston theories, then championed in this country by Joseph Priestley whose style of work is presented in his own writings on "Experiments and Observations on Different Kinds of Air." 1775, where he says: "More is owing to what we call chance . . . than to any proper design or preconceived theory in this business."

Woodhouse was not a chance chemist. He did not look for the proverbial "discovery by accident." He had a fair imagination but did not make Grecian use of it. He labored diligently in his laboratory. Whether he sought an economic use for persimmons or a national source of nitrates, he worked with a scientific procedure of almost modern characteristics. He was not a mere understudy of the European schools; and whatever may have been the motives of Dr. Benjamin Rush in lending his influence in having Woodhouse appointed to the chair of chemistry at Pennsylvania, the name of this successor to Franklin in the scientific circles of our first capitol will be mentioned by chemists with pride.

\* \* \*

**SULPHURIC ACID HANDBOOK.** By *Thomas J. Sullivan*. Pages 240. Price \$2.50. New York: McGraw-Hill Book Company, Inc.

This is the most up-to-date handbook of the numerical data on sulphuric acid. It treats of its subject from the gaging of the volume in vertical or bumped horizontal cylindrical tanks right through the laboratory gravity and temperature determinations and calculations, and finally ends with splendid data on iron and lead acid-proof pipes and fittings.

The recognized standard tables in use in the United States on the Baumé hydrometer scales and the acid gravities etc. (Ferguson and Talbot determinations) adopted by the Manufacturing Chemists' Association of the United States are given. Most of the data on the manufacture of acid, on sulphur, sulphur dioxide gas, nitric and nitrous acid, arsenic, selenium etc. are sufficiently covered for practical application in the plant. All chemists having anything to do with the mineral acids will find their requirements best taken care of by consulting this convenient handbook.

\* \* \*

**THE JOURNAL OF THE INSTITUTE OF METALS,** Vol. XIX. Edited by *G. Shaw Scott, M. Sc.* 316 pages. Price 21s. net. The Institute of Metals, 36 Victoria Street, London, S. W., England.

Among the various contributions published in this volume of the well known *Journal* may be mentioned "The Constitution of the Copper Rich Aluminum-Copper Alloys" by J. Neill Greenwood, and "An Investigation on Unsound Castings of Admiralty Bronze (88:10:2): Its Cause and the Remedy" by Prof. H. C. H. Carpenter and Miss C. F. Elam. An appreciation of the importance of the papers presented at the last meeting of the Institute may be gathered from the fact that the spoken and written discussion occupies much more space than the text of the contributions. Sixty pages of closely printed abstracts of the current literature on non-ferrous metallurgy close the volume, which, needless to remark, sustains the high tone of its predecessors.

## Personal

MR. H. K. BENSON has accepted a captain's commission in the Ordnance Department and has been assigned to the nitrate division for the investigation of the arc process in nitrogen fixation. Captain Benson was formerly professor of industrial chemistry and director of the Bureau of Industrial Research, University of Washington. During the past summer he made a field study of nitrogen products for the American Nitrogen Products Co., Seattle, Wash.

MR. F. W. BRUCKMILLER, formerly assistant professor of chemistry at the University of Kansas, is now chemist for Standard Oil Co. (Indiana) at Sugar Creek, Mo.

MESSRS. ALBERT BURCH and H. W. HARDINGE are in charge, respectively, of the Pacific Coast and Appalachian districts recently created by the U. S. Bureau of Mines for the purpose of making an inventory of manganese deposits and to assist in stimulating production. The country has been divided into four districts. In this same connection, G. H. CLEVINGER is stationed at Golden, Colorado, in charge of experiments in the metallurgy of manganese.

MR. LEONARD W. EGAN, formerly with the Wellman-Seaver-Morgan Co., has severed his connection with that concern and has become associated with the Electric Furnace Company as special engineer.

DR. HARRY S. FRY, formerly associate professor of chemistry, has been appointed professor and head of the department of chemistry at the University of Cincinnati. Other appointments in this department are as follows: DR. EARL F. FARNAU, associate professor of organic chemistry, formerly assistant professor of chemistry at New York University; DR. RALPH E. OESPER, associate professor of analytical chemistry, formerly assistant professor of chemistry at Smith College; DR. CLIFFORD J. ROLLE and DR. LEONORA NEUFFER, instructors in chemistry.

MR. S. GEJSBEEK of the Geijsbeek Engineering Company has been appointed district chief for Oregon, Washington and California for the Industrial Furnace Section, Bureau of Conservation, U. S. Fuel Administration.

MR. L. H. GOEBEL has resigned as superintendent of filtration and chief chemist of the Water Filtration Plant of the Union Stock Yard and Transit Company, Chicago, Ill., to become associated with the engineering staff of Wallace & Tiernan Company, manufacturers of chlorine control apparatus and sanitary engineering specialties.

MR. MAX K. GROSSHEIM has been put in charge of the engineering department of L. O. Koven & Brothers, Jersey City, N. J.

MR. ROBERT GEORGE HALL, formerly general manager of the River Smelting and Refining Co., St. Louis, Mo., has been appointed resident manager of the Burma Mines, Ltd., Nantau, Upper Shan States, Burma.

MR. VANCE McCARTY, for the past twelve years manager of the Pittsburgh branch of Edw. R. Ladew Company, Inc., has been appointed general sales manager of the company, with headquarters in the New York office, 54 Franklin Street.

MR. DWIGHT D. MILLER, formerly with the engineering department of the Society for Electrical Development, New York, is now with the Electric Furnace Co. of America, Alliance, Ohio, as manager of the New York office.

MR. JOHN D. RYAN, president of the Anaconda Copper Co., presented his resignation to the Board of Directors on Sept. 3. As Director of Aircraft Production, Mr. Ryan is now Assistant Secretary of War. Mr. C. F. Kelley will succeed Mr. Ryan as president.

MR. ERNEST B. TALKER is now connected with the Inland Steel Co., Indiana Harbor, Ind., as master mechanic of the furnace plant. He was formerly with the By-Product Coke Corp., South Chicago, Ill.

# Current Market Reports

## The Non-Ferrous Metal Market

**Monday, Sept. 9.**—The metal markets are very steady. The munition consumption gradually approaches the supply, but Government regulation prevents competitive buying by outsiders.

**Aluminium:**—The Government prices on ingots 98 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots; \$662 down to 15-ton lots; and \$660 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40 to 45c.; sheet aluminium, 18ga. and heavier, 42c.; powdered aluminium, 100 mesh, 70c.

**Antimony:**—The recent rise in antimony was but temporary, the price now being 14 to 14½c. for duty paid spot delivery.

**Chrome:**—Western production is now in slight excess of demand. The nominal quotation for 40 per cent ore is \$1.40 per unit, while 50 per cent ore is bringing \$1.70.

**Copper:**—The price of \$520 per ton for car load lots and 27.3c. per pound for small quantities is permanently fixed.

|                            |     |       |          |
|----------------------------|-----|-------|----------|
| Copper sheets, hot rolled  | lb. | \$ 36 | — \$ 37½ |
| Copper sheets, cold rolled | lb. | .37   | — .38½   |
| Copper bottoms             | lb. | .44   | — .45½   |
| Copper rods                | lb. | .36   | — .37    |
| Copper wire                | lb. | .29½  | — .30    |
| High brass wire            | lb. | .28½  | — .29½   |
| High brass sheets          | lb. | .28½  | — .29½   |
| High brass rods            | lb. | .26½  | — .28    |
| Low brass wire             | lb. | .32½  | — .34½   |
| Low brass sheets           | lb. | .32½  | — .34½   |
| Low brass rods             | lb. | .33½  | — .35½   |
| Brazed brass tubing        | lb. | .37   | — .39    |
| Brazed bronze tubing       | lb. | .42½  | — .44½   |
| Seamless copper tubing     | lb. | .41   | — .43    |
| Seamless bronze tubing     | lb. | .45   | — .46    |
| Seamless brass tubing      | lb. | .37½  | — .39½   |
| Bronze (gold) powder       | lb. | 1 00  | — 1 75   |

**Lead:**—The lead market is limited by selling restrictions. Producers must sell at a uniform and pre-arranged price. In car load lots at East St. Louis, the price is \$155 per unit. In New York, all speculative and traders' lead has disappeared. The Lead Committee apportions lead at 8.05c. to legitimate consumers.

**Manganese:**—The scale prices on page 629 of CHEMICAL & METALLURGICAL ENGINEERING, June 15, prevail; the highest price per unit being \$1.35.

**Zinc:**—Spelter continues to advance. East St. Louis is selling at \$183 to \$185 per ton in car lots; New York quotations are from 9.4 to 9.5c. per pound; sheet zinc 15c. and zinc dust (300 mesh) 16c. per pound in 1600-lb. casts.

**Tin:**—Outside tin prices are on the ebb, New York spot being at 80c. This seems to be due to a tendency of consumers to take the reins out of the market's hands and to proportion the available supplies; present prices being believed to be sufficient to maintain the maximum production physically possible. Babbitt metal varies between \$1.00 and 65c.; solder (50-50), 73c. per pound.

**Tungsten:**—The western producers of Scheelite are reluctant in offering at \$25.50 per unit. High grade Wolfgramite is bringing \$25. Off-grade ores vary from \$20, to \$24.

**Silver:**—The Government price of \$1.01½ is hoped to promote production.

### OTHER METALS

|           |        |        |           |
|-----------|--------|--------|-----------|
| Bismuth   | lb.    | \$ 35  | — \$ 65   |
| Cadmium   | lb.    | 1 50   | — 2 50    |
| Colalt    | lb.    | 2 50   | — 3 50    |
| Magnesium | lb.    | 1 75   | — 2 00    |
| Mercury   | 75 lb. | 125 00 | — . . . . |
| Mercury   | lb.    | 1 95   | — . . . . |
| Nickel    | lb.    | 40     | — . . . . |
| Iridium   | oz.    | 175 00 | — . . . . |
| Palladium | oz.    | 135 00 | — . . . . |
| Platinum  | oz.    | 105 00 | — . . . . |

## The Iron and Steel Market

With the total steel requirements for the half year, as estimated by the War Industries Board, increased to not less than 23,000,000 net tons, the supply will reach a shorter distance down the preference list than had been expected. As a matter of fact, in the majority of cases there will be no steel at all for purposes that are not distinguished

except by a place on the preference list. It may be well to explain that while shipments "on the preference list" follow shipments against priorities, the preference list itself is not confined to purposes for which priorities are not given. The preference list includes aircraft, munitions and in fact practically all the most important direct war requirements, for which priorities were for a long time granted individually by the War Industries Board, and for which "automatic priority" was provided in the regulations of last July. All priority business is represented on the preference list, but what are ordinarily classed as preference shipments are those made by virtue of the preference list and not by virtue of priorities.

Thus substantially all the steel shipped is shipped for purposes included in the preference list, but by far the major portion has the priority authority in addition. As to class D, or "permit" steel, which is steel that may be left after the preference list is taken care of, there is, practically speaking, no such thing. In every instance the steel would arise only by the making of off heats or of off material in rolling, and the percentage is very small. As a rule, apparently, mills are disposed to hold such steel on the chance of finding a priority or preference use for it, with its use as scrap as a last resort. Such use, indeed, seems to have been definitely recommended at a recent conference between the War Industries Board and representatives of the steel makers. Scrap being extremely scarce, there is an opportunity of increasing the supply of war steel by such use.

In the case of many producers it is impossible to provide any steel for plain preference purposes, the priority requirements being too extensive. There are many finishing departments that cannot go farther than to take care of all priorities of classes AA and A, with nothing left for the class B priorities, which run from 1 to 8. Steel for replacement of jobbers' stocks, as decreased by priority and preference shipments of jobbers, has B4 priority, and in the case of many mills the supply plays out in that class, the mill being able to ship some B4 steel but not all that has been scheduled. By about the end of August, practically all of the jobbers' August quotas had been scheduled by the mills, but some of the steel will not actually have been shipped by the end of this month.

### PRODUCTION

Production is increasing slightly over the July-August average, which was between 40,000,000 and 41,000,000 tons a year in pig iron and about 42,000,000 tons a year in steel ingots. While the weather was hot, particularly in the first 12 days of August, the curtailment in production on account of high temperatures was less than in any previous summer, the strenuous efforts of managers, foremen and many workmen serving to obviate very largely the relaxation that usually occurs.

In the case of pig iron production there seems to be three restrictive influences—coke, labor and manganese alloys. There has been continued complaint by some furnaces of poor quality coke and there has also been some actual shortage of coke. Both conditions have been taken strongly in hand by the Fuel Administration. For instance, at a meeting in Uniontown on September 4, Warren S. Blauvelt, director of the coke division of the Fuel Administration, met about 200 operators of the general Connellsville region and made a strong plea for the shipment of good, clean coke, urging that steel made now will save human lives by shortening the war. The Railroad Administration is cooperating by endeavoring to furnish absolutely full supplies of by-product coal to the by-product coke ovens, but there is not much to be gained in this respect, seeing that the Geological Survey reports have for months past shown very nearly full supplies, losses in by-product coke output through shortage of coal not having averaged more than perhaps 2 per cent. The efforts do not stop there, however, as there is a larger field for improvement in that as by-product ovens have been completed some beehive ovens have been closed in order to divert the coal to the by-product ovens. If coal from elsewhere can be provided, the closed beehive ovens can resume operations. The seriousness of this situation was brought out early in September, when

the weekly report of coke production, for the week ended August 24, was circulated. Comparing the four weeks ended May 18 and the four weeks ended August 24, there was a decrease in the weekly production of beehive coke of 95,000 tons and an increase in the production of by-product coke of 55,000 tons, showing a net loss of 55,000 tons, this representing, of course, an entirely unsatisfactory state of affairs.

As to labor restricting the production of pig iron, the cases are largely local, chiefly in Virginia, Alabama and Tennessee districts. With respect to the interference of manganese alloys, it is believed in many quarters in the trade that too many furnaces are operating on ferromanganese or spiegeleisen, there being about 20 altogether. It is quite clear that in the market pig iron is much scarcer than ferromanganese or spiegeleisen, and it may be that consumers have large stocks of the manganese alloys besides.

As to steel ingot production, the existing capacity under normal operating conditions could certainly be counted upon for at least 47,000,000 tons a year, whereas the highest rate of production attained has been the 43,500,000-ton rate of June, production in the past two months having been at a somewhat lower rate. On account of limited supplies of scrap and poor quality of what is available, rated outputs cannot be attained, but still it is probable that with an unlimited supply of pig iron more steel could be made.

#### DISTRIBUTION OF STEEL

The War Industries Board names railroad steel as the largest single item in the present requirements, shipbuilding coming second, Army needs, including those of our allies, third, and Navy needs fourth. This of course is not a normal sequence, the high place accorded railroad steel being due to the fact that taking care of the railroads was postponed in favor of more important needs, but cannot be postponed further on account of winter impending. The railroads have been functioning wonderfully well of late compared with their partial breakdown last winter, but cannot be expected to continue doing as well when inclement weather comes.

The combination of heavy rail demands for domestic roads and heavy demands for the A. E. F., an additional 200,000 tons having been ordered for the latter a few weeks ago, rail production is now at a heavy rate, and shell steel manufacture has been largely displaced at some rail mills. At the same time the shell steel requirements have greatly increased, by reason of Marshall Foch's great offensive, and the success the smaller guns have had. A large additional amount of shell steel will therefore have to be contributed by other lines. Two wire departments, Donora and Woodlawn, are being altered for the rolling of shell rounds instead of rod billets, as one contribution. Thus the production of wire will be curtailed and it is probable that production of merchant bars, of standard pipe and of sheets and tin plates will also be curtailed.

#### The Chemical Market

**COAL TAR PRODUCTS:**—The situation underwent but little change during the past two weeks, although of the important crudes benzol was in better demand and supplies are liberal. Chemical prices are inclined to a firmer tone than otherwise. The intermediates in general are in fair demand with prices having an upward tendency due to the restricted offerings.

**Benzol:**—A slight improvement is evident in the buying demand. Considerable interest has been shown in benzol for automobile propulsion which was created through the recent request of the Fuel Administration for the conservation of gasoline. The increase in demand however is not great enough to deplete the large quantities on the market and quotations are 23c. in spot in tank cars and 28c. spot, drums extra and returnable.

**Phenol:**—A quiet market prevails locally but it is said that some large exportations have been made to Japan where the material appears to be urgently needed. Supplies are plentiful and prices are 40c. export drums, but 43 to 44c. drums included are generally quoted.

**Diethylaniline:**—There are more offerings of this product, but buying interest is quiet, with spot material quoted at \$4 f.o.b. works.

**Paraphenylenediamine:**—Movement is running ordinarily; however, available material is limited and dealers offer no encouragement; prices range from \$4.00 to \$4.50 which appears to be about the firm level.

**Acetanilid:**—The demand is not heavy, although for a short period the item has had some activity. Offerings of the material are held at from 68 to 70c. for the U.S.P. and the technical is quoted at 65c.

**Para-amidophenol:**—Trading is seemingly steady and offerings are made by large dealers at from \$4.00 to \$4.50 for the base material.

**Dinitrophenol:**—Producers are concentrating their efforts for Government purposes and supplies are insufficient for immediate requirements. No spot is available and the nominal asking price is 52c.

**Aniline Oil:**—Limited stocks are reported and the demand is fair. Small scattered offerings tend to keep prices at firm levels of about 30c.

**Aniline Salts:**—The product is reported in only fair quantities and second hands are taking advantage of the situation, obtaining a range of prices by no means low for the small amount of material on hand.

**Beta Naphthol:**—Both sublimed and technical grades are in reasonable demand, but the production is not in proportion to requirements. Quotations remain at the firm level of from 80 to 90c. for the sublime and 60c. for the technical material.

**Benzidine Base:**—Offerings are liberal but the demand is only routine, with principal purchases being made for export purposes. Prices are quotable unchanged at \$1.75.

**HEAVY CHEMICALS:**—Trading generally has been fairly satisfactory, with the volume of business apparently on the increase. Prices have had an upward tendency with the exception of some items which are easier and not so firm in demand.

**Soda Ash:**—Consumption requirements are strong and offerings obtainable are being held at strong levels. Considerable speculation is rife and the price asked at New York is \$2.50. Double bags are quoted at works at about \$3.10 with barrels named at prices from \$2.80 to \$3.00. Dense ash from works is reported to be sold as high as \$4 double bags, with other quarters quoting \$3.70 double bags and barrels.

**Salt Cake:**—A lack of consuming interest has resulted with practically no change of position in this market. The general run of selling values is from \$22 to \$25 bulk Northern points.

**Caustic Soda:**—The market was more active during the past two weeks with recent sales at 4c. dock and warehouse. These prices, however, are not considered the market. The Government requirements are becoming more imperative and are now taking about one-quarter of the production. The Government has notified producers that, beginning November 1, their needs will be greater. Therefore, manufacturers have in turn notified firms holding contracts that in view of the priority of Government requirements, deliveries will be curtailed in proportion to the amount required by the Government.

**Yellow Prussiate of Soda:**—The market has not been marked with much change, but lack of demand is evident with regular traders quoting prices from 90c. to \$1.00.

**Bichromate of Soda:**—The situation has been somewhat easier with some business passing at 24c., but no interest is shown in the product at a higher figure.

**Potassium Permanganate of Soda:**—Despite the fact that potassium salt has declined in price to a marked extent, manufacturers of the soda solution continue to quote a price of \$3 per gallon.

**Copper Sulphate:**—Demand has been reasonably active of late with producers having the situation well in hand. Sales of spot have occurred at 9c.

**Sulphate of Alumina:**—A strong situation prevails in this market and consumers who find it necessary to cover are seemingly up against a rising market. Odd lots appear of the iron-free, having sold lately at from 1½ to 1¾c.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, SEPT. 9, 1918

|                                                 |                    |               |        |

## Plant Construction—Catalogs—New Publications

### Construction and Operation

#### Alabama

**BIRMINGHAM**—The Magic City Cotton Co., 10th St. and 12th Ave., North, will rebuild its plant recently destroyed by fire entailing a loss of \$100,000.

**SELMA**—A. G. Kahn Brick Co., will rebuild its plant recently destroyed by fire entailing a loss of \$15,000.

**SHEFFIELD**—The North Alabama Rolling Mill Co., will expend \$300,000 to remodel and enlarge its plant. The company manufactures steel from waste or scrap. This project will be financed by the War Industries Board.

#### Arkansas

**ANDERSON**—Glenn L. Brunner, will build a 40-ton log washer plant for concentration of manganese ore at his mine here, and is in the market for steam shovel, engine, boilers, belts, lumber, roofing, concrete, conveyors, scales, ore cars, wagons for hard ore, jig, pumps, piping and mill hardware. Estimated cost, \$25,000. E. Berry, superintendent.

**BATESVILLE**—The Poke Southern Arkansas Mining Co. will build a 50-ton log washer plant and is in the market for log washer, mill belts, roofing, engine, pump, piping, mill hardware and concrete. Estimated cost, \$25,000.

#### California

**KINGSBURG**—The city has awarded the contract for the construction of a sewage disposal system, including Imhoff tank, to Frederickson & Sharmon, 2323 Washington St., Fresno. Estimated cost, \$27,102.

**LOS ANGELES**—The Thos. H. Ince Moving Picture Co., Hollywood, has awarded the contract for the construction of a reinforced concrete and steel motion picture studio, to include a laboratory, on Washington Boulevard and Sherman Way, to the Milwaukee Building Co., 1006 Pabst Building, Milwaukee, Wisconsin. Estimated cost, \$150,000.

**PASADENA**—The city commissioners of Pasadena, South Pasadena and Alhambra, have awarded the contract for the construction of an experimental sewage disposal plant using the Trent process to L. C. Trent Co., Pasadena. Estimated cost, \$7000.

#### Connecticut

**STAMFORD**—Baer Brothers, 700 Canal St., will build two factories, one on Canal St. and one on Fairfield Ave. for the manufacture of bronze powder. Estimated cost, \$375,000. A. Freeman, 29 West 34th St., New York City, architect.

**WATERBURY**—The Chase Metal Co., Waterville St., will build a 1-story, 40 x 32 ft., brass mill on Thomaston Ave. Estimated cost, \$40,000.

#### Florida

**FORT MYERS**—The Ocean Leather Co., 82 Beaver St., New York City, will build a plant for the manufacture of fertilizer and smoke and cure fish. Estimated cost, \$30,000.

**PENSACOLA**—The Bureau of Yards and Docks, Navy Department, Wash., D. C., will build a photo-laboratory, and oil reclaiming building. Estimated cost, \$620,000.

#### Georgia

**ATTAPELUS**—The Lester Clay Co. will rebuild its fuller's earth plant recently destroyed by fire, entailing a loss of \$100,000.

#### Illinois

**CHICAGO**—The Amalgamated Machine Corp., Racine and 37th St., will build a 1-story, concrete and steel plant for the manufacture of large gun boring machines. Estimated cost, \$500,000.

**GREAT LAKES**—The Bureau of Yards and Docks, Navy Department, Wash., D. C., received low bid for addition to disposal plant from the Embankment Co., Joliet, Ill. Estimated cost, \$31,420.

**MADISON**—The Barker Asphalt Co. has awarded the contract for the construction of a 1-story, 100 x 160 ft. concrete, brick and steel factory, the Austin Co., 1611 Euclid Ave., Cleveland. Estimated cost, \$50,000.

#### Iowa

**MARSHALLTOWN**—The Prier Brass Manufacturing Co., c/o W. H. Prier, will build a 1-story, 60 x 160 ft., brick foundry.

#### Kansas

**BAXTER SPRINGS**—The Buck Shot Mining Co., Miami, Okla., will remove its 250-ton concentration plant from Joplin, Mo., and remodel same. It is in the market for sludge and slime tables, belts, mill hardware, roofing, conveyors, etc. Estimated cost, \$35,000.

**BAXTER SPRINGS**—The Lucky Girl Mining Co., Carthage, Mo., will build a 200-ton concentration plant and is in the market for sludge and slime tables, ore bins, ore cars, ore cans, concrete, lumber, composition, roofing, belts, air compressors, drills, pipe, cables, engine, boilers, conveyors and mill hardware. Estimated cost, \$65,000. Miss Emma Knell, secretary.

**BAXTER SPRINGS**—The Omaha Lead and Zinc Co., Joplin, Mo., will build a 250-ton concentration plant and is in the market for sludge, slime tables, engine, boilers, crushers, conveyors, mill hardware, air compressors, etc. Estimated cost, \$65,000. T. M. Chenoweth, superintendent.

**BAXTER SPRINGS**—The Mississippi Queen Mining Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, belts, lumber, roofing, crushers, engine, boilers, air compressors, mill hardware, conveyors, drills, etc. Estimated cost, \$65,000. W. H. Berry, superintendent.

**TREES**—The Montreal Chuff Mining Co. will build a 250-ton concentration plant on the coal line and is in the market for crushers, belts, wire cables, concrete, wheels, mill hardware, engine, boilers, roofing, air compressors, pipes, pumps, drills, etc. Estimated cost, \$65,000. C. F. Dyke, superintendent.

#### Louisiana

**NEW ORLEANS**—The Bureau of Yards and Docks, Navy Department, Wash., D. C., will build a shell house. Estimated cost, \$40,000.

#### Maryland

**HYATTSTOWN**—The Hyattstown Roller Mills will rebuild its plant recently destroyed by fire, entailing a loss of \$12,000. Mortier and Luhn, operators.

#### Massachusetts

**SPRINGFIELD**—The Hampden Paint & Chemical Co., 317 Main St., has awarded the contract for the construction of a factory addition to the Casper Ranger Construction Co., 20 Bond St., Holyoke. Estimated cost, \$5000.

#### Michigan

**DETROIT**—The General Aluminum & Brass Manufacturing Co., Boulevard and Aubion Sts., will build new units to its plant to include a 2-story, 100 x 100 ft., aluminum foundry, with concrete covers, two brass foundries, one 40 x 100 ft., to be equipped with sand bins and simplex and coke furnaces, the other, 60 x 180 ft., and a 3-story, 60 x 140 ft. machine shop. Government orders have made this addition necessary.

**GRAND RAPIDS**—The Semet-Solvay Co., Milton Ave., Syracuse, N. Y., has awarded the contract for the construction of a 1- and 2-story, reinforced concrete, brick and steel T.N.T. plant, covering 500,000 sq. ft., floor space, to Stone & Webster Co., 147 Milk St., Boston, Mass. Estimated cost, \$2,000,000. Noted Aug. 15.

**MIDLAND**—The city will install a water testing station and plans to install

a filter plant. S. A. Greeley, Schiller Building, Chicago, Ill., engineer.

#### Minnesota

**FAIRMONT**—The city will build a sewage disposal plant including an Imhoff tank and sludge drying beds. E. L. Lewis, city clerk.

#### Missouri

**AURORA**—Sharp & Co. will build a 150-ton concentration plant on Bonanza Lease, and is in the market for sludge and slime tables, crushers, air compressors, drills, belts, conveyors, concrete, lumber, and mill hardware. Estimated cost, \$45,000.

**AURORA**—Stanley & Co. will build a 1-ton concentration plant on Foster Lease, and is in the market for drills, hoists, sludge, tables, boilers and crushers. Estimated cost, \$45,000.

**DUENVEG**—The St. Louis Mining Co., 721 Main St., Joplin, will remodel its 150-ton concentration plant and is in the market for sludge and slime tables, small motors, engine, boilers, crushers, drills, conveyors, belts, mill hardware and roofing, etc. Estimated cost, \$25,000. J. Blair, superintendent.

**JOPLIN**—The Julian Mining Co. will build a 150-ton concentration plant south of Four Corners, and is in the market for sludge and slime tables, crushers, lumber, roofing, air compressors, drills, belts, ore cans, ore cars, engine, boilers, concrete, mill hardware, conveyors, etc. Estimated cost, \$45,000. Charles McDonald, superintendent.

**JOPLIN**—The Kansas Line Mining Co. will remodel its 200-ton concentration plant near Kansas State Line, and is in the market for sludge and slime tables, ore cans, lumber, roofing, mill hardware, crushers, air compressors, belts, drills, conveyors, engine, boilers, etc. Estimated cost, \$40,000. G. Meese, superintendent.

**KANSAS CITY**—The Talbot Reel & Manufacturing Co., 11th Ave. and 13th St., has awarded the contract for the construction of two factory buildings, one 2-story, 55 x 130 ft. and one 2-story, 69 x 130 ft., for the manufacture of sunights and binoculars, to Hoffman Bros., Ridge Building. Estimated cost, \$140,000.

**MANSFIELD**—The Mansfield Mining and Development Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, crushers, belts, drills, ore cans, ore cars, lumber, mill hardware, conveyors and air compressors. Estimated cost, \$65,000. J. R. Sardage, superintendent.

**RICHMOND**—The city will build a filtration plant. J. W. Kirkpatrick, city clerk.

**ST. LOUIS**—The Monsanto Chemical Co., 1500 South 2nd St., has awarded the contract for the construction of a 2-story, 80 x 110 ft. chemical factory, to Jas. H. Bright Contracting and Building Co., 706 Chestnut St. Estimated cost, \$118,000.

**WACO**—The Butler Bros. Mining Co. will build a 250-ton concentration plant, and is in the market for crushers, engine, boilers, lumber, concrete, ore cans, ore track, ore cars, mill hardware, sludge and slime tables, air compressors, pipe and conveyors. Estimated cost, \$65,000.

**WACO**—Frank Danclade will build a 250-ton concentration plant at his mine, and is in the market for sludge and slime tables, crushers, engine, lumber, mill hardware, concrete conveyors, rollers, composition roofing, engine, boilers and drills. Estimated cost, \$65,000.

#### Nebraska

**LINCOLN**—The Board of Regents, c/o J. S. Dales, secretary, Station A., will build a 2-story, 20 x 40 ft., pathology and hygiene building. Estimated cost, \$40,000.

#### New Jersey

**BAYONNE**—The Taintor Manufacturing Co., 1st St. and Lexington Ave., will make improvements and build an addition to its plant for the manufacture of whitening, etc. Estimated cost, \$50,000.

**HARRISON**—The Crucible Steel Co., Harrison, has awarded the contract for the construction of a 1-story, 88 x 120 ft., open hearth building, 1-story, 24 x 30 ft., shipping building, 1-story, 28 x 300 ft., ordinance building, 1-story, 10 x 18 ft., pump house and a 1-story, 10 x 40 ft., oil storage building, on South 4th St. and Ocean Road, to W. H. and F. W. Crane Woolworth Building, New York City. Estimated cost, \$125,000, plus percentage.

**JERSEY CITY**—The Interstate Chemical Co., 12 Bayview Ave., has awarded the contract for the erection of a 1-story, brick

factory and storage building on Garfield Ave. to Wm. R. Whyte, 36 Oakland Ave. Estimated cost, \$15,000.

**NEWARK.**—The Board of Education, City Hall, will build a 3- and 2-story, 250 x 250 ft. rectory and steel vocational school, including a chemical laboratory, on a site near Morris Canal. Estimated cost, \$50,000. L. Sonntag, City Hall, architect.

**NEWARK.**—The Linden Tanning Co. will build a 1-story, 60 x 60 ft. brick factory on Frelinghuysen Ave. Estimated cost, \$25,000. W. E. Lehman, 738 Broad St., architect.

**PAULSBORO.**—The Port Mifflin Ship-building Corporation, Widener Building, Philadelphia, Pa., will build a new ship-building plant to include a 1-story, 60 x 850 ft. plate shop, 1-story, 120 x 175 ft. plate shop, 1-story, 76 x 350 ft. forge shop, 1-story, 60 x 175 ft. copper shop, 2-story, 50 x 200 ft. paint works, 1-story, 100 x 530 ft., erecting shop and a 2-story, 100 x 530 ft., joiner shop. L. A. Gilliam, general manager.

## New York

**KINGS PARK.**—The State Hospital Commission, Capitol, Albany, has awarded the contract for the construction of extension to the hospital disposal plant at Kings Park. The disposal plant at Kings Park, Sewage Disposal Co., 37 East 28th St., New York City. Estimated cost, \$15,037.

**LYONS FALLS.**—Moyer & Pratt has awarded the contract for the construction of a 2-story, 100 x 105 ft. paper mill, to L. W. Charlebois, 541 Main St., Watertown. Estimated cost, \$50,000.

**SPRINGFIELD.**—The Semet-Solvay Co., Mill, has awarded the contract for the construction of a 100 x 200 ft., No. 3 Standard Building, to the Austin Co., 16112 Eucha Ave., Cleveland, O. Estimated cost, \$75,000.

**TOMPKINSVILLE.**—The Bureau of Yards and Docks, Navy Dept., Washington, D. C., will build a laboratory and office building here. C. O. Parks, chief.

## North Dakota

**FARGO.**—The Board of Education, E. Guthrie, clerk, has awarded the contract for the construction of a 3-story, brick and concrete high school to include laboratory. B. H. Heston, City Hall, 716 South 11th St., Minneapolis, Minn. Estimated cost, \$215,000.

## Ohio

**CANTON.**—The Canton Sheet Steel Co. will build an addition to its steel mill to include machine shop, forge shop and rolling mills. Estimated cost, \$75,000.

**CANTON.**—The Timkin Roller Bearing Co., Leubster St., will build a 1-story, 100 x 250 ft. concrete, brick and steel factory. Estimated cost, \$80,000.

**DELAWARE.**—The K. & W. Rubber Co., c/o Ora Keichbaum, Ashland, will build a 2-story, 100 x 200 ft. brick and steel factory, for the manufacture of rubber. Estimated cost, \$75,000.

**CLEVELAND.**—The Boro of New Brighton, New Brighton, Pa., will build a brick and reinforced concrete sewage disposal plant. Estimated cost, \$60,000. R. V. Pratt, 708 Hippodrome Building, engineer.

**CLEVELAND.**—The Hughes-Keenan Co., 260 North Main St., Mansfield, has purchased an acre site and will build a factory for the fabrication of steel here. The company recently increased its capital stock from \$25,000 to \$80,000.

**CLEVELAND.**—The Lake Erie Smelting & Refining Co., 7900 Bessemer Building, has awarded the contract for the construction of a 2-story, 40 x 54 ft., reinforced concrete and steel factory at 7900 Bessemer St., to Riley Construction Co., 806 Leader-News Bldg. Estimated cost, \$15,000.

**LORAIN.**—The Cleveland Macadam Co., 1040 Leader-News Bldg., will build a steel and brick plant and shipyard. Estimated cost, \$50,000.

**SANDUSKY.**—The Ohio Tread & Tire Co. has awarded the contract for the construction of a 2-story, 40 x 80 ft., reinforced concrete and brick factory, to Wm. Dorthach & Bros., Sandusky. Estimated cost, \$20,000.

## Oklahoma

**GARDIN.**—The Amy T. Mining Co., Miami, will build a 300-ton concentration plant, and is in the market for sludge and slime tables, ore cars, crushers, belts, lumber, concrete, mill hardware, air compressors, track, gas engine, boilers, steam engine, wire and cables. Estimated cost, \$65,000. J. Buckley, superintendent.

**GARDEN.**—The Shelton Mining Co. will build a 250-ton concentration plant, and is in the market for boilers, drills, sludge and mining machinery, mill hardware, crushers, belts, etc. Estimated cost, \$65,000. F. Childers, superintendent.

**HOCKERVILLE.**—The Lucky Jennie Mining Co., Miami, Okla., will build a 300-ton concentration plant, and is in the market for electric motors, boilers, engine, belts, slime tables, crushers, air compressors, drills, mill hardware, roofing, conveyors, etc. Estimated cost, \$65,000. G. Sullivan, superintendent.

**HOCKERVILLE.**—The St. Louis Smelting and Refining Co., Baxter Springs, Kan., will build a 250-ton concentration plant, and is in the market for sludge and slime tables, ore cars, crushers, air compressors, conveyors, etc. Estimated cost, \$65,000. R. B. Kropp, superintendent.

**HOCKERVILLE.**—The Union Mining Co. will remove and remodel its 200-ton concentration plant, and is in the market for two electric motors, sludge and slime tables, mill hardware, concrete, roofing, air compressors, drills, pipe and crushers. Estimated cost, \$25,000. Robert Qualls, superintendent.

**MIAMI.**—The Amalgamated Co. will build a 250-ton concentration plant, and is in the market for sludge and slime tables, motors, engine, boilers, crushers, lumber, mill hardware, concrete, roofing, conveyors, drills, wire cables, ore cans and cars. Estimated cost, \$65,000. H. L. Huddston, Webb City, Mo., superintendent.

**MIAMI.**—The Atoka Mining Co. will build a 300-ton concentration plant near Rob White lease, and is in the market for sludge tables, gas engines, crushers, compressors, drills, belts, conveyors, etc. Estimated cost, \$65,000. E. M. Applegate, superintendent.

**MIAMI.**—The Miami Metal Co. will build a 200-ton concentration plant near Picher, and is in the market for electric motor, gas engine, air compressors, belts, mill hardware, mill lumber, crushers, sludge and slime tables, etc. Estimated cost, \$65,000. R. Sadler, superintendent.

**MONARCH.**—The Vanwisser and Warren Co. will build a 250-ton concentration plant, and is in the market for mill hardware, engine, boiler, sludge and slime tables, crushers, conveyors, etc. Estimated cost, \$65,000. J. Warren, superintendent.

**MUSKOGEE.**—The Gasomne Co. will build a gasoline refinery. J. T. May, president.

**PICHER.**—The Golden Rod Mining Co. will build two 250-ton concentration plants, and is in the market for motors, engine, boilers, crushers, sludge tables, air compressors, drills, mill hardware, mill lumber, pipe, roofing. Estimated cost, \$65,000. G. Smoyer, superintendent.

**PICHER.**—The LaSalle Mining Co., Joplin, Mo., will remodel its 250-ton concentration plant, and is in the market for pumps, piping, belts, roofing, sludge tables, cement, lumber, drills, conveyors, crushers, air compressors, etc. Estimated cost, \$20,000. A. E. Eadelaar, superintendent.

**PICHER.**—The Mogul Mining Co., Miami, will build a 250-ton concentration plant, and is in the market for sludge and slime tables, drills, engine, boilers, roofing, lumber, concrete, crushers, air compressors, drills, wire cables, conveyors, ore cans, ore bins, ore cars and track. Estimated cost, \$65,000. A. E. Dunlap, superintendent.

**POTEAU.**—The city will build a filtration plant. C. M. Bagwell, mayor.

**TATUMS.**—The Ardmore Lubricating Oil Co. will build a refinery here and sink test well for oil.

**WALTERS.**—The Blue Ribbon Oil & Refining Co. will build a refinery; capacity, 1000 barrels.

## Pennsylvania

**CHESTER.**—The American Steel Foundries, 30 Church St., New York City, has awarded the contract for the construction of a 1-story, 25 x 60 ft., addition to its foundry at Thurlow Station, near Chester, to R. H. Scroggins & Son, Crozer Bldg.

**GLENSHAW.**—The Pittsburgh Mining Machinery Co., 1st National Bank Building, Pittsburgh, will build a 1-story, 65 x 80 ft., addition to its plant. Estimated cost, \$15,000.

**MARCUS HOOK.**—The National Aniline & Chemical Co. has awarded the contract for the construction of a 2-story, 106 x 196 ft., No. 9 type, modified building, to the Austin Co., 16112 Eucha Ave., Cleveland, O. Estimated cost, \$140,000.

**PHILADELPHIA.**—Baugh & Sons Co., 20 South Delaware St., will build a 1-story,

100 x 300 ft. addition to its plant on Morris St., for the manufacture of chemicals.

**PHILADELPHIA.**—The Fibre-Graphite Manufacturing Co., 34 South 17th St., will make alterations and improvements in its plant on Wakenfield St. Estimated cost, \$5000.

## Rhode Island

**WOONSOCKET.**—The Star Carbonizing Co. will build a 2-story, 52 x 178 ft. brick factory on Diamond Hill road. Estimated cost, \$45,000. W. F. Fountain, North Main St., engineer.

## Texas

**CARLSBAD.**—The Board of Directors, State Tuberculosis Sanatorium, has awarded the contract for the construction of a sewage disposal plant and sewer extensions, to Pault & Campbell, Dallas. Estimated cost, \$23,000.

**TEMPLE.**—The city will build an additional unit at sewage disposal plant. Estimated cost, \$7500. Address The Mayor.

**WACO.**—The city will install a settling basin at filtration plant. Estimated cost, \$26,811. E. L. Fulkerson, manager of city water works.

**WICHITA FALLS.**—J. A. Fisher and others will build an oil refinery, daily capacity 1000 barrels.

## Washington

**SEATTLE.**—C. L. Glasgow, New York City, has awarded the contract for the construction of a 1-story, 61 x 17 ft. construction plant for the manufacture of oxygen gas and welding appliances, on East Marginal Way and Spokane St., to James Clark & Sons, 1000 First St., Alaska Building. Estimated cost, \$50,000.

## Wisconsin

**CABLE.**—The Sunbeam Chemical Co., 1742 Ogden Ave., Chicago, Ill., is building a 75 x 300 ft. factory here, and will add other units later.

**CARROLLVILLE.**—The American Tar Products Co. has awarded the contract for the construction of a 1-story, 60 x 90 ft. factory, to Meredith Bros., 1043 Kinnickinnick Ave., Milwaukee. Estimated cost, \$20,000.

**GREEN BAY.**—The Northwestern Engineering Co., Inc., has awarded the contract for the construction of a 30 x 32 x 160 ft. addition to its fabricating plant, to L. Hanson. Estimated cost, \$80,000.

**MILWAUKEE.**—Becker Bros., 1118 26th St., has awarded the contract for the construction of a 3-story, 64 x 147 ft., brick and mill construction tannery, to Riesen Bros., 1st National Bank Building.

**MILWAUKEE.**—J. Schlitz Brewing Co., 3rd and Galena Sts., has awarded the contract for the remodeling of its carbonic gas plant, to W. Woefflein, 86 Michigan St.

## Canada

## Ontario

**ELMIRA.**—The Elmira Rubber Co. will build an addition to its plant. Estimated cost, \$30,000.

**WALKERVILLE.**—The Walkerville Water Co., Sandurich St., will install a 7,000-gal. tank. Estimated cost, \$250,000. C. D. Brown, 86 Lincoln Road, secretary.

**WELLAND.**—The Dillon Alloys Co., Ltd., 122 Hellens Ave., has awarded the contract for the construction of a 1-story, melting building, forge shop, boiler house, etc., to the Standard Steel Construction Co., Port Robinson. Estimated cost, \$150,000.

## Industrial Notes

**THE HALCOMB STEEL CO.** has opened an office in Room 702, Connecticut Mutual Life Insurance Bldg., 36 Pearl Street, Hartford, Conn. Mr. E. L. Keed will be in charge.

**THE QUIGLEY FURNACE SPECIALTIES CO.**, New York, has secured contract for a powdered coal plant from the Whitaker Glassing Company, Beckwith Bottom Works, West Virginia, to furnish 4 tons of powdered coal fuel per hour to supply 20 furnaces for heating 6-in. shell forgings. This equipment is necessary for larger extensions for future applications in other departments in the mills including boilers.

**THE ELECTRIC FURNACE CO.**, Alliance, Ohio, has opened a New York office at 15 Park Row. Mr. D. B. Mills is in charge.

**THE BOARD OF DIRECTORS OF THE MARDEN, ORTH & HASTINGS CORP.** held a meeting on Aug. 28 at which Mr. Arthur C. Trask was

lected vice-president of the Corporation with headquarters in Chicago. Mr. Trask's resignation as secretary of the Corporation was accepted, and Mr. Walter O. Hastings was elected to this office. Mr. Trask has been seventeen years with the concern. While Mr. Hastings is one of the three members of the partnership which in 1906 took over the business founded by James A. Murdock in 1837. Mr. M. S. Orth, President of the Corporation, is a direct descendant of Mr. M. S. Orth. Within the last few weeks Marden, Orth & Hastings have opened new branches at 1303 Shelby Street, Louisville, Ky., and Union Trust Building, Cincinnati, Ohio.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., announcing the opening of Sept. 3 of a branch office in the Union Trust Building, 15 & H Streets, N. W., Washington, D. C. Messrs. H. W. Knowles and C. W. Yerger will be located at the new office.

## New Publications

THE MACHINERY UTILITIES CO., INC., 501 Fifth Ave., New York City: A bulletin, which is only a general industrial equipment, entitled "The Thrift Book," devoted to the utilization of idle machinery in active industries.

THE DOW CHEMICAL COMPANY, Midland, Mich.: A booklet entitled "Dow Chemicals."

CONCRETE IN ARCHITECTURE AND ENGINEERING, Vol. No. 1, dated Jan. 1918, published bi-monthly by the Portland Cement Association, 111 West Washington St., Chicago, Ill. This Association has also published a booklet on "Concrete Tanks for Oil Conservation."

THE UNCOLORED STORY OF AMERICAN DYES. By John Walker Harrington. This appeared in the Evening Post Magazine, May 11, 1918, and has been reprinted in booklet form by the National Aniline & Chemical Company, Inc., 21 Burling Slip, New York City.

BUILDING CONSTRUCTION. By R. I. Webster. Bulletin No. 25, Vol. XIII, No. 1, dated January, 1918, issued by The Pennsylvania State College's Engineering Experiment Station, reprinted from the Annual Report for 1916-1917.

SCHOOL OF MINES AND METALLURGY, Univ. of Missouri, Rolla, Mo. Bulletin, March, 1918, Vol. 10, No. 2, which is the 1917-1918 catalog.

THE EVOLUTION OF NATIONAL SYSTEMS OF VOCATIONAL REEDUCATION FOR DISABLED SOLDIERS AND SAILORS. Bulletin No. 15, (Reeducation Series No. 3). By Douglas MacMurtrie, issued by the Federal Board of Vocational Education, May, 1918.

REFERENCE MATERIAL FOR VOCATIONAL AGRICULTURAL INSTRUCTION. Bulletin No. 14, Agricultural Series No. 2, issued for the Federal Board of Vocational Education, Washington, D. C.

CASE-HARDENING, issued from the Carnegie Library of Pittsburgh, reprinted from the monthly bulletin, March, 1918.

STANDARD LABORATORY TESTS OF COAL- COKE BYPRODUCTS, issued by the Scientific Materials Company, Pittsburgh, Pa., dealing with acid-wash tests for benzol, boiling-point determinations, coal and coke examinations, apparatus for gas examination, specific gravity, density, size analysis, separating apparatus for light-oil, wash-oil and tar testing and tar-special apparatus for tar testing. This booklet contains 32 pages and is well illustrated.

MONTHLY REVIEW OF THE U. S. BUREAU OF LABOR STATISTICS. Vol. VI, June, 1918, No. 6, issued by the U. S. Department of Labor, Bureau of Labor Statistics, Washington, D. C.

THE BULLETIN, Vol. V, No. 11, Series of 1918, published by the Pennsylvania Department of Labor and Industry, Harrisburg, Pa.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: Platinum and Allied Metals in 1917. By James M. Hill. (Pages 1-21, Mineral Resources, 1917, Part I), published June 21, 1918. Gems and Precious Stones in 1917. By Waldemar T. Schaller. (Pages 887-899, Mineral Resources, 1917, Part I), published June 27, 1918. Bauxite and Aluminum in 1917. By James M. Hill. (Pages 1-9, Mineral Resources, 1917, Part I), published June 27, 1918. Strontium, Barium, Lithium, Selenium, and Tellurium in 1917. By Joseph B. Umpleby. (Pages 23-35, Mineral Resources, 1917, Part I), published June 27, 1918. Strontium, Barium, Lithium, Selenium, and Tellurium in 1917. By James M. Hill. (Pages 5-6, Mineral Resources, Part II), published June 19, 1918. Gold and Silver in 1916 (General Report). By H. D. McCuskey and J. P. Dunlop.

Pages 679-721, (Mineral Resources, 1917, Part I), published May 7, 1918. Fuel Briquetting in 1917. By E. J. Leeger. (Pages 1-11, Mineral Resources, 1917, Part I), published May 6, 1918. Cadmium in 1917. By C. E. Siebenthal. (Pages 49-53, Mineral Resources, 1917, Part I), published July 12, 1918. Sulphur, Pyrites, and Sulphuric Acid in 1917. By Philip S. Smith. (Pages 19-62, Mineral Resources, 1917, Part II), published July 10, 1918.

NEW BUREAU OF STANDARD PUBLICATIONS: Bulletin, Vol. 14, No. 1, being a collection of scientific papers on determination of degrees of purity of bright metals for magnetic standards; thermoelectric measurement of critical ranges of pure iron; study of electromagnet moving coil galvanometers for use in alternating current measurements; standard substances for calibration of viscometers, an "average eye" for heterochromatic photometry, and comparison of flicker and equilibrium of bright metal photometer, emissivity of straight and helical filaments of tungsten; aneroid calorimeter for specific and latent heats; and wave lengths of strong lines in helium spectrum. Scientific Paper 32. Application of Dicyanin to Photography of Stellar Spectra. By Paul W. Merrill. Technologic Paper No. 103. Glass for Protection of Eyes from Injurious Radiations. By W. W. Boblentz and W. B. Emerson. Technologic Paper No. 107. Comparative Test of Chemical Glassware. By T. H. Walker and F. W. Fisher. Circular No. 13. Standard Specifications for Incandescent Electric Lamps. Technologic Paper No. 101. Tests of Large Bridge Columns. By J. H. Griffith and C. G. Francis. Circular No. 12. Price, \$0.30. Technologic Paper No. 113. Determination of Permeability of Balloon Fabrics. By Julius David Edwards, issued June 2, 1918. Paper No. 114. Technologic Paper No. 323. Some Characteristics of the Marvin Pyrhellometer. By Paul D. Foote, issued June 28, 1918. Price, \$0.10. No. 74, entitled "Copper" issued June 25, 1918. Price, 20 cents, sold through the Superintendent of Documents, Government Printing Office, Washington, D. C.

NEW BUREAU OF MINES PUBLICATIONS: Bulletin 164, Law Serial 14, Abstracts of Current Decisions on Mines and Mining. Reported from September to December, 1917. By J. W. Thompson. Technologic Paper 184, Weights of Various Coals. By S. B. Flagg. Technologic Paper 189, Temperature-Viscosity Relations in the Ternary System of Oil-Alcohols. By Alexander Field and P. H. Royster. Technologic Paper 144. The Quick Determination of Incombustible Matter in Coal and Rock-Dust Mixtures in Mines. By C. Fieldner, 1917. By J. W. Thompson. Technologic Paper 102, Mining and concentration of carnotite ores. By K. L. Kithil and J. A. Davis. Bulletin 140, Occupational Hazards in the high pressure plants of the convention, based on records of accidents at blast furnaces in Pennsylvania in 1915. By P. H. Wilcox. Bulletin 155, Oil-storage tanks and reservoirs, with a brief discussion of losses of oil in storage and methods of prevention. By C. P. Bowie. Technologic Paper 170. The diffusion of oxygen through stored coal. By S. H. Katz. Technologic Paper 172. Effects of moisture on the spontaneous heating of stored coal. By S. H. Katz and H. C. Porter. Technologic Paper 191, Report of the Committee on the Standardization of Mining Statistics. Compiled by Albert H. Fay.

THE JONATHAN BARTLEY CRUCIBLE CO., Trenton, N. J., issue a well illustrated and instructive booklet on Graphite Crucibles for Foundry Practice.

MICHIGAN COLLEGE OF MINES, Houghton, Mich.: Year Book, 1917-1918. Announcement of courses for 1918-1919.

SOUTH DAKOTA STATE SCHOOL OF MINES, Rapid City, South Dakota, April, 1918: Annual catalog 1917-1918, with announcements for 1918-1919.

NEW U. S. DEPARTMENT OF THE INTERIOR BULLETIN: Mineral Resources of the United States in 1917. Part I. By James M. Hill. 1917. By C. E. Siebenthal; 6, "Gold, Silver, Copper, Lead and Zinc in the Eastern States in 1917," by James M. Hill. Part II. By James M. Hill. Pyrites and Sulfuric Acid in 1917," by Philip S. Smith; 5, "Magnesia in 1917," by Charles G. Gale and Ralph W. Stone; 6, "Talc and Soapstone in 1917," by D. L. Dyer; 7, "Graphite in 1917," by Ralph W. Stone; 8, "Graphite in 1917," by Henry C. Ferguson; 13, "Mica in 1917," by Waldemar T. Schaller.

THE HORTON INDUSTRIAL DIGEST is the new publication of E. F. Houghton and Co., Philadelphia, Pa., dated August, 1918. This publication will be issued every month.

one issue will deal with "textiles" and the next issue with "metal working," etc.

THE EFFECT OF ADDITION AGENTS IN FLOTATION. A bulletin dated Nov., 1917, from the School of Mines and Metallurgy, Rolla, Mo. Most of the material in this bulletin appeared in METALLURGICAL AND CHEMICAL ENGINEERING, in the Dec. 15, 1917, Jan. 15, 1918, and Mar. 1, 1918, issues.

"FUEL FACTS" is the name of a new publication published by the United States Fuel Administration, Washington, D. C. This is dated Aug. 1, 1918.

"TUNGSTEN" is the title of an attractive illustrated booklet issued by the TUNGSTEN PRODUCTS MINING CO., Boulder, Colo.

"THE GLASS INDUSTRY AS AFFECTED BY THE WAR" is the Tariff Information Series—No. 5, issued by the United States Tariff Commission, Washington, D. C., and deals with new branches of the industry, changes in manufacture and trade due to war conditions, holding export and domestic trade after the war, the glass trade of European countries, and testimony of leading American manufacturers.

ANALYSIS OF CANADIAN FUELS. Compiled by Edgar Stansfield and J. H. H. Nicolls. Bulletin No. 23 issued by the Canadian Department of Mines, Ottawa, Canada.

NEW BUREAU OF MINES PUBLICATIONS: Bulletin 145, Measuring the temperature of gases in boiler settings. By Henry Kreisinger and J. F. Barkley. Technologic Paper 187. Slag viscosity tables for blast-furnace work. By L. L. Felt and F. H. Royster. Bulletin 123, Analyses of mine and car samples of coal collected in the fiscal years 1913 to 1916. By Arno C. Fieker, Howard L. Smith, J. W. Paul and Samuel Sanford. Technologic Paper 91. A convenient multiple-unit calorimeter installation. By J. D. Davis and E. L. Wallace. Monthly statement of coal-mine production in the United States for 1918. Compiled by Albert H. Fay. This booklet gives a list of permissible explosives, lamps, and motors tested prior to June 30, 1918. Price, \$0.05.

## Manufacturers' Catalogs

THE CHICAGO BELTING CO., Chicago, Ill., has issued an attractive catalog entitled "To Users of Belting" which contains 80 pages, giving views of its plant and a brief description of the various processes used in making belting.

UNITED IRON WORKS CO., Kansas City, Mo.: Bulletin No. 418, describing and illustrating Pomona duplex journal power pumps.

THE GILBERT & BARKER MFG. CO., Springfield, Mass.: Catalog B illustrating and describing its different types of gas furnaces. This company's process for burning fuel oil under low pressure.

THE TORSION BALANCE CO., New York City: Catalog No. 34 on "Torsion Balance," illustrating the many different balances.

THE HYDRAULIC PRESS MFG. CO., Mount Gilead, Ohio: Catalog No. 43 which describes and illustrates H-P-M hydraulic valves and fittings, hydraulic presses, pumps, accumulators and intensifiers for every high-pressure purpose.

THE DUST RECOVERING & CONVEYOR CO., Cleveland, Ohio, calls attention to Bulletin No. 5, August 1, 1918, on pneumatic conveying.

T. SHRIVER & CO., Harrison, N. J., has issued an attractive catalog on filter presses for all purposes. The catalog contains 44 pages and is well illustrated.

LEEDS & NORRUPH CO., 4901 Stenton Ave., Philadelphia, Pa. Catalog 87, entitled "The Potentiometer System of Pyrometry and Temperature Control," contains 60 pages and is illustrated with half-tones and charts. This catalog deals with potentiometer indicators, curve draw-ers, recorders, multiple point readers, temperature control apparatus, transformation point apparatus, precision potentiometers, thermocouples and optical pyrometers.

THE PYROELECTRIC INSTRUMENT COMPANY, 636 East State Street, Trenton, N. J., calls attention to Circular No. 11 on the Northrup-Ajax High Frequency Induction Furnace which are available in small units for laboratory and scientific investigations.

THE EASTMAN-BLESSING COMPANY, W. Austin Ave. at La Salle St., Chicago, Ill., has issued a catalog on Rego welding and outting apparatus, which gives prices of apparatus.

### The Chemical Exposition and Our Daily Service

At the moment we can think of no industry other than the chemical that could focus attention for a week in war time on a national exposition held in the country's metropolis. It signifies a growing appreciation of the fundamental and basic importance of chemistry in industry and the arts. It is not too much to say that preparations for the event have been under way for a year, for with the closing of each exposition there has been a general reservation of space for the next, and only a short respite before actual plans have been laid for the exhibits themselves.

This year a further tribute to the importance and great public value of the Exposition was paid by the action of the Government itself in permitting the management to proceed with the arrangements in spite of the fact that the great building in which the exposition is held has been commandeered for a military hospital and is undergoing alterations while the show is in progress. Probably no manufacturers in the country are busier than those in the chemical and metallurgical industries. Their time and their products are precious. Labor is scarce and transportation expensive. And yet in spite of all these unnatural drawbacks, busy men have found time to prepare exhibits that are at once interesting to the layman and instructive to the technologist; railroads have transported tons of machinery and material; and the tangible evidence of America's approach to chemical leadership and industrial independence is gathered together in one vast "Exhibit A."

To fail adequately to preserve a record of such an achievement and reflect to the country at large the growing greatness of our chemical industry would be a misfortune indeed. The Exposition would most nearly fulfill its purpose if it could be produced in every important industrial center in the country. This being obviously impossible, it remains for some agency to carry the Exposition to the people, reflecting its activities and reporting its daily proceedings as a tremendous educational force.

Realizing that the full story could never be told in a single issue of this journal, and sensing the need for a timely exponent of the Exposition, we decided to render the service through a series of five daily magazines in which should be expressed some of the prominent phases of our chemical industry. These are identical with the topics for the daily symposia at the Exposition, and comprise: Dyestuffs, explosives and acids; potash; ceramics; metal industries; and industrial organic chemistry. On the subject of explosives we cannot present as much material as we would like, for obvious reasons, but the issue will contain some up-to-date information.

Potash independence is a vital matter to the United States and in the daily devoted to that subject we present what we believe to be the most complete symposium yet compiled. The story of the development of the ceramic industries likewise is typically American and wonderfully encouraging. In metals and alloys we have long held high rank, but the war has stimulated endeavor and produced some new achievements which we record. Finally in organic chemistry in the arts and industries, we recognize a phase of growing importance, and in the issue for Oct. 1 will be found a variety of evidence of this fact. On the whole, the series will constitute a service unparalleled in the records of chemical journalism, but one that is fully justified by the unusual conditions demanding it.

### Statistics of the Chemical Industry

Statistics are notoriously unpopular, so much so that speakers always apologize for inflicting them on an audience, and writers refrain from reference to them except in case of urgent necessity. Statistics also are the subject of a certain type of joke, which will readily come to mind, because like isolated passages from the Scriptures, almost anything can be proved by them; also they are grossly referred to as a form of prevarication.

However these things may be, we make no apology for devoting our first Exposition Daily to consideration of the economic, financial and business side of the chemical industry, with a number of pages devoted to its statistical features. There are several reasons why we consider such a presentation timely and sufficiently important to warrant a special issue.

In the first place, intelligent participation in an industry, particularly one that is expanding as rapidly as the chemical industry, requires more than guesswork when it comes to basing future hopes on past performance. Ask almost any small manufacturer what he knows about the production, imports, exports, sources of supply, market for products and general economic conditions in his industry, and we venture to say his reply will show a general, though not necessarily profound, ignorance of the fundamental facts. On the contrary, let a well-managed manufacturing corporation contemplate a new departure in its business, and again we venture the assertion that before reaching a decision it will have studied the despised statistics carefully to see whether the venture is worth while and offers a reward commensurate with the required risk.

Submit the essential economic facts of an industry to analysis and you will have statistics as an important residue after the more volatile and less important elements have been distilled. As basic facts you will have some expression of quantity and value which will measure the importance of the industry for you. Compare and analyze the residue and you will gain information not otherwise obtainable.

The only statistical yard-stick we have for our chemical industry is the census of manufactures for 1914. Although the figures are readily obtainable they are not widely distributed and used. Believing that they should afford a basis for many a sound business survey during these years of expansion, we bring them to the attention of the chemical industry feeling that the effort is warranted once in five years.

Another feature in this issue is an analysis of the chemical industry by the economist and statistician of a great financial and business institution. Banks are following the chemical industry closely, both in its domestic and foreign aspects. A special contributor deals with the latter phase of the industry. No less important is the announcement of the work undertaken by the American Chemical Society to give us adequate information on our imports of raw materials for the chemical industry, as well as finished products. The ultimate achievement of the ambitious plans which the Society has laid out will be worthy of the largest chemical society in the world, in what we firmly believe will become the greatest chemical nation in the world.

### Wanted: Public Appreciation of the Chemical Industry

One of the greatest functions of the chemical exposition, particularly in this fifth year of the war, is the education of the general public to a proper appreciation of the importance of chemistry in our national life. If there were no other benefits to be derived; if chemists themselves and their technically trained colleagues gained nothing through inspection of the exhibits and listening to learned discussions; if the industry did not profit in a material way from the efforts expended in the great show; if none of these things resulted, the time and labor involved would still be well spent if the people of the United States would begin to think of our nation in terms of chemistry.

We do not mean to inflict the technical language of the profession on the public, but we do mean that there should be more than a slight comprehension of the fact that chemistry lies at the bottom of industrial independence, and that for the future welfare of our people we must recognize this fact and give it support in matters pertaining to education, legislation, economics and politics. We mean that the public should see to it that the chemist as an individual citizen plays a more important part in our affairs; that he is consulted in matters affecting our national life; that he is even forced out of the retirement of his laboratory and made to function in the body politic.

It has been said in extenuation of the chemist's failure to play a more prominent part, that his work is best done in retirement and seclusion and that he acquires a habit of modesty that prevents him assuming a public rôle. But if the chemist has been backward and modest, his shortcomings are as nothing compared with the failure of public appreciation of his work. Nor is this a new story; it is as old as chemists and chemistry. Elsewhere in this issue we reproduce the words of a wise man of Philadelphia who told his colleagues one hundred and twenty years ago that the United States could never achieve true independence until chemistry played a large part in the country's development. This was spoken but a few years after the revolutionists had thrown off the rule of the mother country and had assumed the rôle of an independent nation. Political independence was a prize worth fighting for, but it required the vision of a chemist to foretell the futility and weakness of an independence not founded on the rock of chemistry. What chemists want today as then, is a public support and appreciation of the fact.

# Opening Exercises at the Chemical Exposition

## Verbatim Report of Addresses Made by Leaders of the Chemical Industry Touching on Important Public Problems

THE Fourth National Exposition of Chemical Industries was formally opened to the public Monday afternoon, Sept. 23, 1918. The event was signalized by the gathering of a notable body of men who are devoting their time to the application of chemistry in the cause of democracy. The chemical societies were represented by their presidents with the exception of Dr. William H. Nichols, President of the American Chemical Society, who was unable to attend. We present herewith, practically in full, the remarks of the principal speakers.

### Permanent Chemical Independence

BY CHARLES H. HERTY  
Chairman Advisory Committee

THIS annual assemblage of the products of American chemical industry and of the mechanical appliances by which these products are manufactured provides fitting occasion for a stock-taking of past accomplishments, and a care-taking for the perman-

CHARLES H. HERTY

understanding is produced which creates a sound, intelligent public opinion, which is the greatest asset any industry can possess.

The number of exhibitors continues to grow, in keeping with the continued expansion of the industry throughout the nation. The only disappointment is the setting aside by the Railroad Administration of the large plans which had been inaugurated by the industrial departments of the several railroads for presenting here a marvelous display of those natural resources of this country which still await the touch of the chemist to rise to their true dignity as invaluable assets. It has been deemed necessary to eliminate during war times this most promising and well inaugurated line of development.

In taking stock of the chemical industry first thought turns naturally to the matter of available capital. The amount of capital accessions has continued to grow. During the first eight months of 1918, \$59,164,000 was added, making the aggregate authorized capital invested in the industry since August 1, 1914, the date of the outbreak of the war, \$386,967,000.

These figures do not include, of course, the investments made by the national Government in the great chemical plants whose output is used solely for war purposes. The total production of these plants sets our Government apart as the largest manufacturer of chemicals in the world. In the after-war period when the story may be told of the rapidity of construction and of the enormous output of these plants it will add a brilliant chapter to the romance of chemistry. Meanwhile we can rest content in the assurance that the great army which we are now hurrying to Europe will be abundantly supplied.

Perhaps the picture of the growth of the industry can best be gathered from a few figures concerning our export trade, for export statistics indicate production in excess of domestic needs, great as these demands have been during the past year. Four items have been selected, three because of their fundamental character, and one on account of the rapidity of its development.

| Exports                      | 1913/1914      | 1917/1918       |
|------------------------------|----------------|-----------------|
| Sulphuric acid               | 12,000,000 lb. | 68,000,000 lb.  |
| Caustic soda and soda ash    | negligible     | 334,000,000 lb. |
| Benzol                       | negligible     | 25,000,000 lb.  |
| Dyes, dyestuffs and dyewoods | \$357,000      | \$17,000,000    |

Doubtless in future years these figures will appear diminutive, but at present they constitute an inspiring hope for that future.

A fair measure for that increasing participation of the Government in chemical activity is shown in the supplemental appropriation estimates submitted by the War Department to Congress on September 17, 1918. Aside from the great appropriations for explosives there has been requested for the Chemical Warfare Service, the recently organized division having to do solely with offensive and defensive gas warfare, \$198,-

ency of those additions to our national wealth whereby economic independence may be assured. To secure this independence it is essential that there should be close cooperation between the chemist and the American people, which can only be brought about when the chemist takes the people into his full confidence regarding the problems whose successful solution is a matter of joint responsibility. By the presentation of these exhibits and by open discussion of the problems confronting the industry a sympathetic

704,000, a sum greater than was asked for the clothing of the increased army we are now raising. Germany began poison gas warfare; within the next twelve months it will have more than its fill of it.

#### PUBLIC SUPPORT

The present status of the American chemical industry and its prospect for the future must prove gratifying to all good citizens of this republic, but these prospects can never be fully realized unless the work of the chemist is supported by sound and loyal public opinion, which, in turn, will eventually manifest itself in the form of a thoroughly sympathetic attitude on the part of official representatives of that public opinion.

The stress of war preparations and the great part we feel that we are destined to play in the decision have aroused a wholesome national pride, which should contribute to the development of an atmosphere of good-will. America must make good! America can make good! America shall make good! These thoughts fill the minds of our people to-day. The craze for "imported goods" which has so often palsied industrial effort is now being supplanted by pride in domestic achievement. Certainly the label "Made in Germany" no longer exerts its hypnotic influence over the masses of the world. Yet German propaganda is insidious, is ever present, and must constantly be combatted if we are to gain that measure of national self-containedness in essential industries which will guard us against a recurrence of the economic tribulations which characterized the period immediately following the blockading of German ports. The chief centers of that disturbance were coal-tar chemicals (dyes and medicinals), and potash; and I beg to ask your serious attention to certain conditions attending the efforts to create these industries in this country.

#### DYES AND GAS WARFARE

No word is needed concerning the marvelous development of the dye industry. It is here to-day for your inspection. Nor need I dwell upon the close relation of this industry to that of high explosives. That point has already sunk deep into our national consciousness. It was appreciation of this relation perhaps even more than economic need, which brought together producers and consumers in a unique display of unanimity which procured from Congress a protective tariff and anti-dumping legislation which guaranteed life for the young industry.

There was an additional argument for such legislation, however, undreamed of by any of us at that time. We had not entered the war, and gave no thought to the efforts which might be required of us in the matter of poison gas production. But when our authorities, following our entrance into the war, determined to meet the Germans with their own weapons and on a scale far greater than they had ever contemplated, it became necessary to make use of every available means for manufacture of toxic material. The great plants planned for government construction and operation were not sufficient for the program. I am violating no confidence in telling you that at this juncture the Government turned to the young dye industry for plants and trained organiza-

tions to augment its poison gas output, and splendidly has the young industry responded. For military reasons I am advised not to mention specific plants or the products manufactured therein, but with official sanction I may say that five dyestuff plants are now participating in the production of this material, while many others are contributing indirectly to the same end. The plants were suited to the needs, staffs and workmen were familiar with this kind of work, and the process of conversion to the new rôle was thus enabled quickly to be made.

In view of the adaptability of the dyestuff industry to such serious national needs, it is difficult to be patient with many of our mercantile establishments which still insist upon placarding their counters with signs such as "The color of these goods cannot be guaranteed." What a sweet morsel of comfort these placards are to the enemy, in effect an effort to preserve the market for him, by our own people, if such they are! Was it ever the practice to guarantee all colors? Certainly not, for even before the war nine-tenths of the dyes used were not fast and did not need to be. Moreover, are our merchants not yet aware of the conditions which led for a time to the uncertainties as to color fastness? Do they not know that in the period of acute shortage of German dyes, before the American industry was started, many German dyes were used for purposes never intended, and so gave bad results, in most cases falsely attributed to American origin, and so when remaining German stocks approached depletion, and the American products began to appear on the markets, these were likewise used in ways never intended, with equally as poor results as in the case of the misuse of the German dyes. With the present adequate domestic production, these matters are correctig themselves. Public sentiment can, and I believe will, make an end of the disloyal placards.

#### NEEDED LEGISLATION

Assurance of the future of the coal-tar chemical industry lies not only with our people as a whole but even more directly with their representatives in Congress, for it must not be forgotten that legislation stands to-day, as a result of the enactment of the 1916 general revenue bill, which is directly in favor of the German industry, the risk of the very life of the American industry. Every phase of the domestic industry has been studied by the Tariff Commission, and, according to a recent statement of a representative of the Commission, its report to Congress will be published soon after the passage of the revenue bill. While nothing is known of the character of this report, I am confident that when the results of this impartial study of the industry are presented to Congress the same unanimous vote will characterize the correction of errors of existing legislation as has just marked the passage by the House of the eight billion dollar revenue measure. But the time for action is short if we achieve the great military victory in 1919 to which all look forward with supreme confidence. No opportunity must be afforded for the practice of industrial infiltration which may sap the very foundations of the coal-tar chemical industry.

In this connection may I suggest the legislative correction of an error for which we chemists are primarily

responsible. In the existing act intermediates are assessed one-half the duties of finished dyes, which ratio was adopted by Congress upon our recommendation. Experience has shown that this differentiation is a mistake. The difficult stage of production is from the crudes to the intermediates, far more difficult than from the intermediates to the finished dyes. And it is in the field of intermediates that dyestuffs, high explosives and medicinals meet upon common ground. Furthermore, it is evident that when these industries bear the brunt of foreign attack the enemy will take advantage of questions of definition to avoid the higher duties, or will seek to accomplish the same purpose by shipping the lower assessed intermediates for assemblage here into finished dyes by simple processes requiring little outlay. Justification of this contention is furnished by the following extract (page 22) from the "Census of Dyes and Coal-Tar Chemicals 1917" just issued by the Tariff Commission:

With these exceptions the American dye industry was based entirely on imported intermediates. . . . This peculiar situation was due primarily to the provisions of the tariff laws of 1897, 1909, and 1913, which have consistently placed a higher duty on dyes than on intermediates. In general the German industry dominated the field and the Americans were unable to compete. It happens, however, that in the making of certain dyes the last chemical step of transforming the intermediate into the finished dye is a comparatively simple and cheap process. As the rate of duty on intermediates was lower than that on the finished dyes, the margin in some instances was sufficient to make it profitable to avoid paying the higher duty on dyes, by importing the intermediates and completing the manufacture of the dyes in the United States.

Knowing therefore where the attack will be made, would it not be the part of wisdom for us to strengthen our forces at this point by legislation which will place all of these products on the same dutiable basis?

#### COAL-TAR MEDICINALS EQUALLY IMPORTANT WITH DYES

Coal-tar dyes have received an abnormal amount of attention from our people and our press. Of equal importance and of far greater meaning to the comfort and well-being of our people are the coal-tar medicinals. In spite of unfavorable legislation our manufacturers have worthily met their responsibilities in this field. Especially is this noted in the recent statements of government officers that the needs of our Army for these materials had been fully met by our home output. Congress, I am again confident, will correct the unevenness in legislation which hangs as a life-threat over this line of production.

In spite of the lack of coöperation during the past three years some progress has been made. The 1000 tons of  $K_2O$  produced in 1915 was increased to 9720 tons in 1916 and 32,000 tons in 1917. Much fundamental investigation has been carried out, and the promise for the future is hopeful. Success can be predicted if producers and consumers get together, and if public opinion is aroused to the fact that failure to secure national independence in this matter vitally affects the entire nation. The mining bill, as modified by Senator Henderson, and now before the Senate, may prove the solution. It may be that protective duties or direct subsidy will be called for, or possibly the relief of capital invested in this industry from war

taxation. What ever the cost and whatever the method adopted, Government assistance is needed and may be secured if the demand is nation-wide. Independence in potash can be assured if this country makes up its mind that it will no longer be dependent upon Germany for its supplies, but its mind must be made up quickly. This is one of the most urgent questions, in both its economic and its political aspects, before this country to-day. We cannot afford to neglect it.

## Importance of Chemistry in Industry

BY G. W. THOMPSON

President American Institute of Chemical Engineers

THIS National Exposition of Chemical Industries, the fourth that has been held, is a growing illustration of the advantage to our industries which chemistry has afforded. The growth of our industries of all kinds has been greatly assisted by chemists. Strictly speak-

G. W. THOMPSON

ing, all industries are chemical industries, but some are more obviously chemical industries than others. This exposition has to do naturally more with the industries which are obviously chemical, but the general proposition that all industries are dependent upon chemical processes should be emphasized, even if in each case the connection is not obvious to the unthinking man.

We learn by adversity. This war has taught us that all industry is more or less chemical in its character. The fact that the assistance of chemistry has been particularly demanded during the last four years has been due to the fact that our most powerful enemy has been perhaps a little wiser than we have been in the past; and we, seeing the extent to which chemistry could be of service to a nation, both in war and in peace, have learned a lesson, although our education in this respect may not be complete. If chemistry has been of great assistance to us during this war, how much more will it be of assistance to us when the war is over and we are again in competition with a great commercial enemy that earlier learned the lesson of which

I am speaking. The few remarks that I have to make today are in the direction of trying to impress upon our people the necessity of learning this lesson more completely, learning it from day to day, learning it with respect to war and with respect to peace.

Every one needs instruction along this line, but I will address myself particularly, first, to those who control manufacturing operations; second, to the universities and colleges where chemists are taught; and third, to chemists themselves. Those who control manufacturing operations must learn more fully and completely the need of chemical knowledge for the perfection of industry, the need of chemists in their organization. Our universities and colleges must learn that however valuable pure chemistry may be as an interesting study and for the purpose of training the mind, the most important thing that chemistry does is to be found in its application; that while it is extremely interesting and upbuilding to think in terms of atoms and molecules, it is equally important to think in terms of large quantities of the chemical components that enter into reactions. Chemists must learn more fully and completely the need of applying their knowledge to chemical processes conducted on a large scale.

Permit me to elaborate my appeal for a greater education of these three groups of individuals. Again, let me speak to those who are at the head of concerns that control manufacturing operations. They will, without doubt, agree to the broad academic statement that I have already made, that all manufacturing industries are chemical to a greater or less degree and that for their successful prosecution the chemist is an essential factor. Some manufacturers are more progressive than others in this respect, and they are the ones who have made the greatest success in recent years. This academic statement, however, is to be valued by its application. Manufacturers need chemists and they should do everything in their power to secure a supply of the best chemists possible. The progress of manufacturing is dependent upon the development of chemical knowledge, and manufacturers should give their assistance in every way in their power to the development of chemical knowledge.

Manufacturers can do a great deal to help the universities and colleges in developing more efficient methods of instruction. They can do this by calling university and college professors into their councils and developing the practical sides of these professors so that the students in their charge will be developed along lines which will be useful to industry. The teacher in chemistry who is not in touch with practical manufacturing operations cannot properly instruct the student under him and build him up so as to make him capable, on graduation, of entering into the industries and applying his knowledge to their furtherance.

Practical business men often distrust college professors. They say that they are theoretical and visionary. This in many cases is due to the fact that the practical business man has a narrow vision. Sometimes it may be true that instructors in chemistry have not a practical turn of mind. Whether this view of practical business men is true or not, the remedy is in their hands, and if they will see their broad duty, they will throw open their plants more freely to instructors in chemistry and make the education of chemists a part of their

organized plan. In other words, our colleges and universities must be used by our manufacturers and our manufacturing plants must be opened to use by our universities and colleges.

Now, let me address another word to our educational institutions. They are not entirely free from criticism. It is my opinion that the educational institutions of this country should give honorary degrees to men who have accomplished big things in the industrial world. The practice in many of these institutions is to give degrees only to those who have done original work in what is called pure science but which work may be of no immediate practical use. It is my opinion that the man who discovers by hard labor things of practical value in the chemical world is deserving of some recognition from our colleges for his contribution to practical science.

I believe that our universities and colleges should, all of them, turn more to the practical aspects of education. Many of them think only of its cultural side. Culture is desirable; no one questions this, but culture is not incompatible with an education that suits a man for the practical affairs of life. It is absurd to say that a man, to be successful in the business world, must be a boor, for its corollary is that the man of culture cannot succeed in the business world. Culture with an education that will make the student of practical use is what we want, and the educational institution that thinks only of culture is about as bad off as the educational institution that thinks only of the practical affairs of life. Our educational institutions should keep in touch with manufacturing operations, and instructors in chemistry should keep their feet upon the earth, even if we cannot expect them at all times to keep their heads out of the clouds.

Since this war started it has been a wonderful thing to see how chemists generally have offered themselves to our Government in the hope that they would be able to help in solving the practical problems confronting it. Many instructors of academic chemistry descended from their exalted positions and attempted to handle problems which they, by experience, have been unfitted to solve. All honor to these men; we do not criticize them, and have only praise to offer for their self-sacrifice. How much better would it have been, however, if these men had been better acquainted with the practical matters with which they became intrusted. They came nobly to our country's assistance. They broke down the barriers with which they were surrounded, and it is a delicious hope that when peace arrives they will not allow these barriers again to be erected.

To chemists generally I address this word: You have the power of influencing the opinion of manufacturers, those that control industries and the opinions of those who control the policy of our educational institutions. I would ask you to insist upon it that the manufacturers of our country and our educational institutions get closer together and that between them there be opened up wide avenues of intercourse. The result will be that each will be modified. Our industries will be influenced by our educational institutions and our educational institutions will have breathed into them some of the life of the business world.

We all know that this exposition is to be a success, but success in the best sense of the term involves the

power of growth. Success does not consist only in the doing of single definite things, but in the bigger sense means the doing of a series of definite things, each member of the series being of a greater value than that which immediately preceded it. My few remarks are directed to the desire that chemists and chemical industries, and expositions of this kind will have the vitality and growing power so that each succeeding achievement will surpass that which preceded it, in a progressive and developing series.

## America's Supremacy in Electrochemistry

By F. J. TONE

President, American Electrochemical Society

**D**URING the past four years we all must agree that the chemical industry of America has passed through the most important period of its history. This has been a war not only between efficiently organized armies and nations but between efficiently organized in-

in spite of the strong position of the industry before the war no one would have dared to predict the expansion which the war would demand of us. It has called for chlorine, cyanamide, air nitrates and phosphorus in vast quantities. It has required the ferro-alloy industry, the electrode industry, and the abrasive industry to quadruple their outputs.

As a single example, consider briefly the contribution of electrochemistry and electrometallurgy to the aircraft program. The airplane motor has a crank case and pistons of aluminium. Its crank shaft and engine parts subject to the greatest strains are all composed of chrome alloy steel. All of these parts are brought to mechanical perfection and made interchangeable by being finished to a fraction of a thousandth of an inch by means of the modern grinding wheel made from electric furnace abrasives. Calcium carbide and its derivative, acetylene, are making possible an ample supply of cellulose acetate for airplane dope. When the aviator trains his machine gun on an enemy plane his firing is made effective by tracer bullets of magnesium or phosphorus. When our bombing planes begin to carry the war into Germany, it will be with bombs perhaps of ammonium nitrate or picric acid or other high explosives all depending largely in their manufacture on electrochemical reagents. Without the pioneer work of Hall, Acheson, Willson, Bradley and others, the present aircraft program would be absolutely impossible of achievement.

Then there is gas warfare, the very basis of which is chlorine. Germany has long been a nation of chemists and when she planned a war of frightfulness it followed as a matter of course that she should seek to make it also a war of chemical frightfulness. Much as we deplore it, therefore, we have been forced to throw our best energies to the solution of the problems of gas warfare. It is interesting to note that chlorine, the product of the electrolytic cell is the basis of mustard gas, chlor-picrin, phosgene and almost all of the important war gases. Thus does electrochemistry enter fundamentally into the modern military machine.

It is important for us to remember that while we are working to develop our industry to a point where it will meet the demands of the war, our work is only begun. If this is, in a measure, a chemists' war we must work to see that afterwards we have a chemists' peace. After the war will come bigger problems and bigger responsibilities; no one will have a bigger opportunity than the chemist to make life better and to serve his fellow man. We have the problems of the conservation and proper utilization of our resources, the elimination of wastes, the problems of foodstuffs, clothing and sanitation. All these problems and many others touch the everyday life of the people and are pre-eminently the problems of the chemist. Fortunately the nation is coming to realize to what an extent it depends in war and in peace on the work of the chemist. By the establishment of the Chemical Warfare Service, our place in the military organization has been definitely recognized. We want the same recognition in the councils of the nation after the war. We want the Government to recognize the value of scientific methods and we will look to this exposition in future years as one of the forces which will visualize to the rest of the country the role of the American chemist.

F. J. TONE

industries. Our chemical industry today is pitted against the chemical industry of Germany and one has only to study this great exposition to be convinced that the American chemist is going to measure up to his opportunity. At the beginning of the war our industry was highly organized in special fields but it lacked symmetrical development. It was unbalanced. It lacked self-containedness and coördination. It has taken the war to enable the chemical industry to find itself and it has likewise taken the war to enable this country to discover that it has a great chemical industry and to recognize it as a great national asset; and it must be said that one of the big forces which have worked toward the progress of chemistry and toward public recognition of chemistry in America has been this exposition. We give all honor to the men whose foresight and energy made this possible.

In this big forward movement of the past four years the electrochemist has played a large part. America has long enjoyed a supremacy in electrochemistry, but

# The Chemical Industry in Export Trade

**The American Manufacturer Must Study Foreign Conditions and Be Prepared to Meet the Most Exacting Requirements of Foreign Buyers. The Chemist Must Commercialize His Abilities in a Higher Degree**

By G. A. O'REILLY

Foreign Trade Representative Irving National Bank, New York

THE after-the-war foreign-trade problem to be solved by the chemical industry of this country is about the same as the big general problem which must be solved by all the other industries which hope to operate successfully in the foreign field.

The details involved in the process to be considered are well known to the experienced, and must be provided for in domestic trading as well as in that which concerns foreign fields. A market must be found, sufficient information concerning the essential conditions affecting that market must be secured, the product must be manufactured with proper reference to the requirements of the particular market, and there must be secured such a cost of production, treatment and distribution as will make it possible to meet the competition of similar products that may be coming from other sources of supply.

Some of our American industries have solved this foreign-trade problem and have mastered the essential details concerned with considerable thoroughness. Steel, oil, copper, tobacco, cotton, several machinery, equipment and appliance lines, and certain of our special lines have reached the point in foreign trade success where they are able to meet the keenest foreign competition to be met.

It will be found, too, that a large number of American general lines also have been introduced and distributed in the foreign field in a manner which contributes most effectively to our foreign trade standing, but in many such cases success accomplished has resulted not from the activity of manufacturers, nor from any intelligent appreciation on their part of the problems to be solved in foreign markets, but from the efforts of the highly developed class of institutions known as export commission houses.

From the earlier days of our experience with world markets, houses of this class have figured most importantly in the development of American foreign trade. They have studied the foreign field, have come to understand its requirements, have created organizations capable of treating the difficulties of credit, transportation and distribution and, in general, through the intelligent development of facilities, have effectively bridged the commercial chasm which under other conditions would separate the greater portion of our American product from foreign markets in which it might be absorbed to the benefit of all parties concerned.

In recent years there has been developed among even smaller American lines a disposition on the part of manufacturers to break away from export commission houses, and deal direct with the foreign customer. In many such cases, where the entire situation has been thoroughly understood results have been satisfactory but in others, where the particular manufacturer as-

sumed that there was in his situation some quality of merit which would justify him in disregarding the experience of the export commission house concerning facilities actually required, difficulty has been encountered.

If the manufacturer wishes to deal direct with his foreign customer, he will find it entirely practicable to do so, but in so doing he must realize that in each transaction there is required a more or less standard unit of facilities. In other words, if he depends upon some short cut to success, he is apt to be severely disappointed.

Of course there are among our products those whose natural popularity in world markets is so great that these markets will make almost any effort, however unreasonable, in order to get them. This condition of affairs is particularly noticeable at the present time when the demands of war must be satisfied regardless of price or convenience or anything else. It will be found, though, that even in the most conspicuous of these cases, steel, oil, etc., the necessities of the foreign purchaser have not been allowed to interfere with the development of American facilities of distribution. Indeed, in point of completeness of facilities all along the line, these major industries are among the most highly developed in existence.

## NO EASY ROAD OR SHORT-CUT TO SUCCESS

This rather extensive reference to the general aspect of American foreign trade bears upon the future of the chemical industry in world markets as showing that there is no easy or cheap way of achieving success. From the beginning, clear through to the end of each foreign trade transaction there are certain requirements which must be met, certain classes of service which must be provided. Whether they are to be provided by the manufacturer, by the jobber, by the export commission house, or otherwise, is unimportant in this discussion—the important thing is that they be provided.

The markets of the world must be surveyed and studied so that the particular product concerned will operate abroad under most favorable instead of the least favorable conditions. The wishes, tendencies, and even the peculiarities of the particular market selected must be considered as of fundamental importance. If a particular population wants a product in a certain condition or in a certain size or color, or even in a certain class of container, it is up to the American manufacturer and exporter to recognize these requirements, otherwise it will be found much better to select some other market. It will not be enough to provide a good product, even a better product than the foreign market has in mind. This is particularly true of

Oriental peoples. Like the man in the song, "They want what they want, when they want it."

#### OUR CHEMISTRY MUST BE COMMERCIALIZED

Nor is there anything in the chemical situation which will justify any disregard of these requirements upon their part. As far as the difficulties to be encountered are concerned, theirs is just a plain, ordinary foreign-trade problem, with perhaps an occasional new element of difficulty which is not encountered in other lines. It will not be enough to assume that the foreigner does not know what he wants—not enough to assume that he will be content with a leftover portion of some product which has been manufactured without any intelligent reference to his needs or wishes or whims, and above all it will be fatal to success to assume that he is under any obligation to reconcile his points of view or standards or business policies with ours. If we wish to play with him we must recognize the rules of the game as he understands them. If not, we must make up our mind to play with someone else. It is a very practical case of the old idea of "fish or cut bait."

Quite naturally, and because of certain conditions for which nobody in particular is to blame, but which are in the situation nevertheless, the chemical industry in its relations with the foreign market has more to do, more to overcome than the average American industry similarly interested. In a very considerable sense, and excepting a rapidly growing number of chemical concerns, this industry has not yet been commercialized. Certain of its products are well established in the domestic market, and in the foreign markets as well—certain of the great commercial concerns of the country have specialized in the commercial treatment of chemical products as highly as has been done in any industry, but in general, a large part of the industry still seems to be on a professional rather than a commercial basis.

#### CHEMISTS SHOULD CONTROL THE CHEMICAL INDUSTRY FROM A TO Z

When we realize the almost mysteriously professional nature of the processes which result in the creation or preparation of the chemical product, it is not difficult to see why the commercial end of the industry, as far as at least as the old school type of chemist is concerned, should be given a position of secondary importance only. But on the other hand, when we realize the ease with which in these times, and under modern methods of operation, the experimenter or discoverer becomes in turn a manufacturer, a financier, a distributor, it is not easy to understand why such a large percentage of the really high-class members of the chemical industry should be satisfied to be called in by some concern for the solution of certain of its problems, or with executing one or two of the perhaps numerous processes involved in completed commercial treatment, or with any other participation which stops short of proper control of the industry and a proper share in its profits.

This is only a layman's view of the case, and there may be perfectly good reasons why the situation is as it is, but the prodigies of accomplishment which were so clearly shown in the chemical exposition of last year in this city, leave no doubt in the mind of the layman as to the class of ability represented in that industry. It

is difficult to believe that these men who have done these impossible things should find it necessary to shy at the much simpler tasks of financing industries, or distributing their products. The chemical industry of this country in relation to foreign trade still is in its early infancy. It required a world war to puncture the bubble expressed in the theory of a necessary dependence upon Germany. What a wail went up when our American business discovered that the war had cut off our former German source of supply for dyes, and how skeptical nearly everybody was concerning the possibility of that supply being replaced from domestic sources within reasonable time—and how beautifully it all has worked out, and how easy it all seems now, and how independent we feel of Germany and all the other countries of the world, not only as regards dyes, but in at least a dozen other lines, for which before the war we had depended almost absolutely upon the intelligent enterprise of foreign lands.

#### SHARP COMPETITION WILL RETURN AFTER THE WAR

And now, after a while, the war will be over—the markets of the world will be opened, commercial monopolies such as we now know so intimately no longer will exist, or at least will be seriously disturbed; competition again will come back into the field, real competition, sharper perhaps than we have known in the past. Our world-known and commercially established chemical products probably will continue popular in the markets of the world, but this will not be enough. The lessons of the war regarding the possibilities of our own people must not be lost. Our chemical industry should claim in the markets of the world the same privilege which in the past this country so freely accorded to the chemical products of other countries.

In this process, best results in the chemical industry will be possible only when the chemist realizes that after all he and not the financier who invests, or the distributor who exports is the important element in the case. Professional he must remain, but not to the exclusion of the other impulses and qualities which the commercial world recognizes as indispensable to commercial success.

#### German Industry and the War

The *Société de Chimie Industrielle* has recently issued a special number dealing with German industry and the probable effects of the war upon it. The industrial condition of Germany before 1914 is described, and the excellent means now being adopted to better her position are pointed out, high tribute being paid to her spirit of investigation and organization. Finally, Germany's post-war aims are reviewed, and the lessons that France and all the Allies have to learn are put forward very strikingly and clearly. It is shown that Germany is concentrating all her attention upon measures for regaining her position in the world markets, and the need for reform in the training of science students in France is emphasized. Laboratory work and chemistry generally need more encouragement, and, as in England, science and industry must be brought into closer co-operation. It is an encouraging sign that the *Société de Chimie Industrielle* is rapidly increasing in membership and resources, and its efforts deserve and will no doubt attain to success in the highest degree.—*Chemical News*.

## The Slow Growth of Public Appreciation

### An Account of the First Campaign For the Chemical Independence of the United States — The First "Nitrate" Committee

By BERNARD C. HESSE, Ph. D.

THE American public has at last discovered its chemists! The importance of the chemist and of chemistry in science and every-day life seems now to be fully realized, at any rate suitably acknowledged, by the American public. That this did not take place until 1914 is in no way due to failure of the chemist to tell the public how important he and his science are, but to his inability to make the public give heed to him, as the following extracts from "Chemistry in America," by Edgar F. Smith, Provost of University of Penn., show.

On April 11, 1798, just over 120 years ago, Thomas P. Smith in closing his Annual Oration before the Chemical Society of Philadelphia, the first chemical society in the world of which any record remains, said:

"I shall now, gentlemen, conclude with a few observations on the utility of a general diffusion of chemical knowledge throughout America.

"Living as we do in a new, extensive, and unexplored country, separated by an immense ocean from all other civilized nations, we must feel ourselves deeply interested in a knowledge of *its* mineral productions, and this can only be arrived at through the medium of chemistry. As far as our very limited knowledge has yet gone, we have every reason to believe that nature has been far from bestowing her blessing upon it with a parsimonious hand. Abounding as it does with the richest ores of the most valuable metals, we should be committing a crime of the blackest dye, were we through *willful ignorance* to trample under foot these invaluable gifts of the Creator.

"The only true basis on which the INDEPENDENCE of our country can rest are AGRICULTURE and MANUFACTURES. To the promotion of these nothing tends in a higher degree than chemistry. It is this science which teaches man how to correct the bad qualities of the land he cultivates by a proper application of the various species of manure, and it is by means of a knowledge of this science that he is enabled to pursue the metals through the various forms they put on in the earth, separate them from substances which render them useless, and at length manufacture them into the various forms for use and ornament in which we see them. If such are the effects of chemistry, how much should the wish for its promotion be excited in the breast of every American! It is to a general diffusion of a knowledge of this science, next to the VIRTUE of our countrymen, that we are to look for the firm establishment of our INDEPENDENCE. And may your endeavors, GENTLEMEN, in this cause, entitle you to the gratitude of your FELLOW-CITIZENS."

During all the years since the American chemist has conscientiously lived up to the admonitions of Thomas P. Smith, he has done his appointed share. *The public alone did not respond.*

Five Philadelphia chemists on February 3, 1798 advertised "to the citizens of the United States" that in the interest of public benefit they would analyze free of all charge any minerals sent them. They did this pursuant to a resolution formed by the Chemical Society of Philadelphia certainly made arrangements for public work in the most patriotic spirit, and the record shows that they accomplished much. In 1799 the same Society appointed a committee of three (two of them among the preceding five) to get together all information as to domestic sources and modes of manufacture of niter, an indispensable ingredient of gunpowder. Here was the fore-runner of the "Nitrate Committee" recently appointed by President Wilson to determine how best to make "nitre" from the air. In 1802 the same Society offered a medal, at a cost of \$50, to the person who could produce the best specimen of clay for potters' ware in the United States.

Nor were the chemists of those days recluses; most of them were active in other professions and sciences, in politics, religion and in public affairs of many kinds. Nor were they "woman-haters" as the following, published by Smith in 1789 and earlier, show:

"I shall now present you with the last and most pleasing revolution that has occurred in chemistry. Hitherto we have beheld this science entirely in the hands of *men!* we are now about to behold *women* assert their just, though too long neglected claims, of being participators in the pleasures arising from a knowledge of chemistry. Already have Madame Dacier and Mrs. Macaulay established their right to criticism and history. Mrs. Fulhame has now laid such bold claims to chemistry that we can no longer deny the sex the privilege of participating in this science also." And again:

"Chemistry is a science particularly suited to women, suited to their talents and their situation; chemistry is not a science of parade, it affords occupation and infinite variety; it demands no bodily strength, it can be pursued in retirement; it applies immediately to useful and domestic purposes; and whilst the ingenuity of the most inventive mind may be exercised, there is no danger of inflaming the imagination; the judgment is improved, the mind is intent upon realities, the knowledge that is acquired is exact, and the pleasure of the pursuit is a sufficient reward for the labour." (Letters for Literary Ladies, before 1798).

*The American chemists of more than one hundred years ago said it all! How similar to what we have repeatedly heard as being "news" since 1914? The outlines of the picture as a whole were all supplied by them; filling in the detail was all that was left to do; the American chemist of today has done that and has always done it well. May the American public never again lose sight of its chemists!*

## Side-Lights on the Exposition

THE show, as a thing in itself, looks familiar. The Buffalo Foundry is in its old place on the main floor at the western end, the National Aniline is in its old place at the east end, south of the main entrance while the du Ponts have taken greater space than heretofore to the north of the entrance. The Norton Company is where it was and so are J. P. Devine and Co., Arthur D. Little, Inc., the General Bakelite Co.—and then comes the Barrett Co. moved over next to them. These and many other names are growing familiar even to those who visit the show to learn chemistry. The exhibits themselves on the other hand, display the greatest diversity from previous Septembers. Not only in things but in the manner of exhibiting them there has been a material change since 1914. The main purpose of the undertaking was to enable manufacturers to improve their methods and technique with materials and apparatus of which they had not been theretofore informed, and to discover how their activities might be extended; but it has gone much further than this. Exhibitors are using all kinds of devices to explain not only what they make but, as far as it is reasonable to tell, how they do it. In a first, hurried glance around the Grand Central Palace and without looking at a single exhibit thoroughly, we obtained the general impression, somehow, that the public was a great school and the exhibitors were competitive teachers. Earnest efforts are made to explain the relations of materials to each other.

\* \* \*

On the second floor, or rather the main balcony, the Chemical Warfare Service of the U. S. Army has an exhibit in charge of Major F. E. Breithut, formerly a professor at the College of the City of New York. In thirty feet of space along the corridor it displays more particularly the developments in chemical warfare, in which everyone admits the Germans were the pioneers. In many respects we have learned to view with doubt the German claims for chemical originality; to reconsider the manifold boasts to which we formerly listened with attentive and credulous ear, and to subject them to a generous discount. But poison gas and torture gas as munitions of war are products of German Kultur and if we only believed that the Kaiser is right and that he speaks the truth, we should be constrained to acknowledge that their introduction has been accomplished under Divine guidance.

Our gas warfare is carried out under the auspices of two divisions; defensive and offensive. Originals and photographs of the various allied types of masks as well as those of the enemy are shown. The new American type is also displayed and its future use in mines is clearly indicated. Offensive gas warfare is also represented by specimens of shells and grenades of many sorts.

They are designed for the various different types—sneeze, mustard lethal, phosphorous (for incendiary work and to produce white smoke) and others. An oval form of shell is shown among others that may fall into any position without becoming a dud, which is a shell that fails to explode. We may have more to say about these things later in the week.

## Program of Fourth National Exposition Chemical Industries

Grand Central Palace, New York  
Week of Sept. 23, 1918

The addresses comprise a series of symposiums devoted to a consideration of

THE DEVELOPMENT OF CHEMICAL INDUSTRIES IN THE UNITED STATES, NOTABLY SINCE JULY, 1914.

Tuesday, September 24th

Afternoon (2:30 P.M.) Symposium: ACIDS and CHEMICAL ENGINEERING.

E. J. PRANKE (American Cyanamid Co.), Development of Nitric Acid Manufacture.

EMERSON P. POSTE (Elyria Enameled Products Co.), Developments in the Manufacture of Glass Enameled Apparatus.

Evening (8 P.M.) Motion Pictures.

THE OIL INDUSTRIES

\*The Story of a Cake of Soap.

\*Light from the Rocks; Natural Gas (4 reels).

Lake Asphalt Industry (Barber Asphalt Co.).

Asphalt Roofing Industry (Barber Asphalt Co.).

Asphalt Colloids (Barber Asphalt Co.).

(9 P.M.) Speakers:

J. A. SWITZER (University of Tenn.), Waterpower Potentialities of East Tennessee.

HERBERT C. HENEGAR (American Zinc Co.), Mineral Resources of East Tennessee. (Representing Knoxville Chamber of Commerce.)

Wednesday, September 25th

Afternoon (2:30 P.M.) Symposium: POTASH.

C. A. HIGGINS (Hercules Powder Co.), Recovery of Potash from Kelp.

LINN BRADLEY (Research Corporation), Recovery of Potash from Iron Blast Furnaces and Cement Kilns by Electrical Precipitation.

JOHN W. HORNSEY, Potash from Desert Lakes and Alunite.

ALFRED DE ROPP, JR. (American Trona Co.), Potash from Searles Lake.

Evening (8 P.M.) Motion Pictures.

Electrical Precipitation of Potash from Cement Dust (Research Corporation).

\*Colloid Chemistry.

The Operation of a By-Products Coke Plant (2 reels). (H. Koppers Co.)

Moving a Forest to France (4 reels). (Southern Pine Association.)

The Story of Potash—Production at Searles Lake.

# The Economic Importance of Our Chemical Industry

The Chemical Industry Has Shown Wonderful Ability to Expand to Meet Unusual Demands Created by the War—Has Grown Much Faster Than Our General Manufacturers — United States Acquiring a Position of Independence

By FREDERICK A. CLAWSON

Economist and Statistician, The National City Company

IN 1914, the United States imported \$137,180,000 of chemicals, explosives etc., while the exports were only \$65,696,000, leaving a net excess of imports over exports of \$71,484,000. In 1916, exports were \$914,072,000, or an increase of \$848,376,000, while imports had increased only \$50,860,000, making a net increase in domestic production, due to increased exports, of \$797,516,000, or 67 per cent of the entire manufactures of 1914. In the same period petroleum production increased 9.8 per cent and coke production 57 per cent.

## EXPANSIVE POWER OF THE CHEMICAL INDUSTRY UNDER SUDDEN DEMAND

The chemical industry of the United States has shown greater efficiency and greater powers of quick response to business demands than almost any other of the great industries of the country. War requirements have made special demands upon our chemical industry, and that it has responded with great promptness and in a way evincing great possibilities of expansion is illustrated by the fact that exports of chemicals in 1917 were practically seven times as great in value as in 1914, the year immediately preceding the war, while exports as a whole were only three times as great as in 1914. Government figures of all chemicals, drugs and dyes exported from the United States were, in the fiscal year 1914, \$27,079,000; in the fiscal year 1917, \$187,846,000 and in the fiscal year 1918, \$180,000,000. Even this does not tell the full story because the great group called "explosives," in which the growth has been far more striking, is so closely allied to the chemical industry as to be in fact a part of it, and in explosives the growth is from \$6,272,000 in 1914 to \$820,000,000 in 1917, and to \$400,000,000 in 1918. While perhaps we would not class cartridges, gunpowder or dynamite as strictly "chemicals" the fact that the group which includes all of the unenumerated articles now included under the general head of "other explosives" grew from less than \$1,000,000 in 1914 to \$420,000,000 in 1917, and to \$37,000,000 in 1918, shows that in the industries closely allied with chemicals the growth has been quite as striking as in chemicals proper. In the articles which may be considered as strictly "chemicals" the growth in exports illustrates the great expansive power of this branch of our industries. Acids, for example, exported in the fiscal year 1914 amounted to less than one-half million dollars in value, in 1915 \$3,000,000, in 1916 \$24,000,000, in 1917 \$55,000,000, and in 1918 approximately \$48,500,000. Dyestuffs, of which we expected to be in very great need by reason of the cutting off of the usual source of supply from Germany, actually showed very large gains in exports, the total value of exports of dyes

and dyestuffs having grown from one-third of a million dollars in 1914 to over \$1,000,000 in 1915, more than \$5,000,000 in 1916, \$12,000,000 in 1917 and \$16,500,000 in 1918, and this exportation, it should be understood, of \$16,500,000 worth of dyes and dyestuffs in the fiscal year 1918, occurs exclusively in domestic products, and does not include any foreign dyes re-exported.

Soda salts and preparations, of which the exportation was so small in 1914 that the Government did not find it necessary to make a record, jumped to more than \$3,000,000 in the fiscal year 1915, \$12,600,000 in 1916, \$18,000,000 in 1917, and to \$22,950,000 in 1918. That mysterious group "all other chemicals" in which are included many new articles chiefly for war work, grew from \$9,000,000 value in 1914 to \$22,500,000 in 1915, \$56,000,000 in 1916, \$75,000,000 in 1917 and \$42,000,000 in 1918. These figures are cited especially to illustrate the expansive power of this, one of the most important of the manufacturing industries of the United States.

## COMPARISON WITH OTHER GREAT INDUSTRIES

The importance of the chemical industry is evidenced by comparison of the amount of capital and value of products turned out with that of other leading industries. The value of capital of the group known as "chemicals and allied industries" as shown by the census of 1915 was in 1914 \$723,000,000, and that of the group distinctly classed as "chemicals" \$224,000,000. Let us compare these two totals—\$723,000,000 for "chemicals and allied industries" and \$224,000,000 for the distinct group known as "chemicals"—with those of some of the other great industries. In the great woolen, worsted and felt goods manufacturing industry the total capital in 1914 was but \$413,000,000, or but a little more than one-half that of all chemical and allied industries. In the silk-goods industry, which turns out \$250,000,000 worth of goods per annum, the capital invested was but \$210,000,000 as against \$224,000,000 in the group strictly known as "chemicals." The total capital of the great automobile industry in 1914 was but \$408,000,000, or little more than one-half that of "chemicals and allied industries," while that of the great flouring mill industry, which turns our grains into condition for food was but \$380,000,000 or but about one-half that of "chemicals and allied industries." Even the great cotton manufacturing industry, which turns more than one-third of our enormous cotton crop into form for use shows a capital of but \$900,000,000, or a little more than that of "chemicals and allied industries."

The growth of the chemical industry is illustrated by the fact that the total capitalization of "chemicals and allied industries" as shown by the 1915 census was more than 9 times as great as in 1880, and more than 3 times

as great as in 1900, the figures of capital for "chemicals and the allied industries" having been in 1880, \$86,000,000; in 1900, \$239,000,000; and in 1915, \$723,000,000, while the value of the product turned out was in 1880, \$99,000,000; in 1900, \$263,000,000, and in 1915 \$548,000,000.

#### GROWTH OF INVESTED CAPITAL, LABOR AND VALUE OF PRODUCTS

This comparison of the growth of capital with that of value of products turned out calls attention to some extremely interesting facts with reference to the requirements of capital in this great industry, and the disposition to substitute capital for labor in production, as is the general custom in all of our industries. A comparison of the census figures of capital, number of employees and value of products turned out in the distinctly "chemical" industry (not including the group known as allied products) shows that the capital employed has increased much more rapidly than the number of men employed. The census of 1880 shows the number of employees in the distinctly chemical industry at 11,000 and in 1915, 37,782; while the capital stated in 1880 was \$29,000,000 and in 1915 \$224,000,000; thus the number of employees in 1915 was but about three and one-half times as many as in 1880, while the stated capital invested in the industry was in 1915 nearly eight times as much as in 1880; the increase in number of employees was 243 per cent and in capital 672 per cent. The value of products turned out in the strictly "chemical" industry grew from \$38,600,000 in 1880 to \$158,553,000 in 1915. In the group "chemicals and allied products," the capital grew from \$86,000,000 in 1880 to \$723,000,000 in 1915, and the product turned out from \$99,000,000 in 1880 to \$548,000,000 in 1915.

Attention is especially called to the fact that in the gradual substitution of capital for labor, in this as well, as in other industries, the amount of capital utilized in turning out a dollar's worth of material is materially greater than formerly, although the amount of labor used in turning out a dollar's worth of material is distinctly less than formerly. In the group "general chemicals" the amount of product turned out for each dollar of capital invested was in 1880 \$1.33, and in 1915 but 70c. for each dollar invested in the industry. In the great group "chemicals and allied products" the amount of products turned out for each dollar invested, as shown by the census of 1880, was \$1.15, and in 1915 74c. for each dollar invested, while as already indicated the increase in labor employed was at a far less rate than that of capital.

It is in the power of our chemical industry to rapidly enlarge its products and to quickly respond to the demands made upon it as this great industry develops, but unfortunately we are unable to closely measure the growth resulting from the demands of the war, since the latest census (that of 1915) relates to the operations of the calendar year 1914, of which only a small part was sufficiently within the area of war activities to have been materially affected in the matter of its output. The only means of measuring the growth since the census, is by the value of chemicals exported, which grew from \$27,000,000 in 1914 to \$46,000,000 in 1915, \$124,000,000 in 1916, \$187,846,000 in 1917 and approximately \$180,000,000 in 1918, this estimate for 1918, be-

ing based upon official returns for 11 months and an estimate for the closing month of the year. Meantime the importation of chemicals show only a moderate growth, though this slow growth in chemical imports since the war began is probably due in some degree to the fact that the markets of Germany, from which we brought large quantities of this class of merchandise, are no longer open to us. Chemicals imported have increased from \$83,000,000 in 1914 to \$120,000,000 in 1917, a gain of about 50 per cent in imports, while exports of chemicals increased over 500 per cent during the war period to 1917. Chemicals imported reached \$150,000,000 in 1918, a gain of about 70 per cent in imports, while exports of chemicals increase over 540 per cent.

#### UNITED STATES THE WORLD'S GREATEST EXPORTER OF CHEMICALS

A very large proportion of the chemical industry is found in the section east of the Mississippi. In New York State the group "general chemicals" in the year 1910 (the latest year for which we have figures in detail) were \$35,000,000, New Jersey \$22,000,000, Pennsylvania \$16,000,000, Michigan \$13,000,000, Ohio \$8,000,000, Massachusetts \$6,000,000 and Illinois \$5,000,000, all of these figures being in very round terms. It is not practicable to compare with any degree of accuracy the chemical industry of the United States with that of other countries by reason of the fact that the classification or groupings by the different countries of materials of this character differ so radically that the group termed "chemicals" in the official returns of one nation is liable to differ radically in the articles included from that of other countries. Prior to the war the United States was looked upon as one of the world's greatest importers of chemicals and held a comparatively low rank in the exportation of chemicals, especially when compared with certain European countries, notably Germany, France and Great Britain. Since the war the exports of chemicals of the European countries have of course greatly declined and their imports increased, and as a consequence the United States doubtless stands at the present moment as the world's greatest exporter of chemicals when measured by total value. This leadership of the United States in the world's export trade of chemicals must be considered as probably only temporary, though the enormous growth in our exports of chemicals does suggest great possibilities awaiting that industry in supplying the demands of the importing world.

Tables I, II and III show the imports into the exports from the United States of chemicals from 1910 to 1918, also the production of the group classed as "general chemicals," and of the greater group known as "chemicals and allied industries" as shown by the United States census figures for each census year from 1880 to 1915.

TABLE I—IMPORTS AND EXPORTS OF CHEMICALS INTO AND FROM THE UNITED STATES 1910 TO 1918

| Fiscal Year | Imports      | Exports      |
|-------------|--------------|--------------|
| 1910        | \$76,803,000 | \$21,416,000 |
| 1911        | 79,751,000   | 23,007,000   |
| 1912        | 77,123,000   | 25,117,000   |
| 1913        | 94,241,000   | 26,575,000   |
| 1914        | 88,039,000   | 27,079,000   |
| 1915        | 79,250,000   | 46,381,000   |
| 1916        | 109,123,000  | 124,478,000  |
| 1917        | 124,770,000  | 187,846,000  |
| 1918*       | 150,300,000  | 180,000,000  |

\*June estimated

TABLE II—PRODUCTION OF GENERAL CHEMICALS IN THE UNITED STATES AND CAPITAL EMPLOYED

| Census of | (U. S. Census Figures) |                                | Employees | Wages and Salaries |
|-----------|------------------------|--------------------------------|-----------|--------------------|
|           | Capital                | Product per Dollars of Capital |           |                    |
| 1880      | \$29,000,000           | \$38,600,000                   | \$1 33    | 11,000             |
| 1890      | 55,000,000             | 59,400,000                     | 1.08      | 17,100             |
| 1900      | 89,100,000             | 62,700,000                     | .71       | 21,200             |
| 1905      | 96,600,000             | 75,200,000                     | .77       | 22,600             |
| 1910      | 153,100,000            | 117,700,000                    | .75       | 27,600             |
| 1915      | 224,355,000            | 158,053,000                    | .70       | 37,782             |

TABLE III—PRODUCTION OF GENERAL CHEMICALS AND ALLIED PRODUCTS AND CAPITAL EMPLOYED, 1880 TO 1915

(Allied products include fertilizers, explosives, dyestuffs, essential oils, wood distillates, sulphuric and nitric acids, carbon, bone and lampblack, and paints and varnishes) \*

|      | Capital      | Product per Dollars of Capital | Value of Product per Dollar of Capital |
|------|--------------|--------------------------------|----------------------------------------|
| 1880 | \$86,000,000 | \$99,000,000                   | \$1.15                                 |
| 1890 | 180,000,000  | 125,000,000                    | .69                                    |
| 1900 | 238,500,000  | 202,500,000                    | .84                                    |
| 1905 | 324,100,000  | 281,000,000                    | .90                                    |
| 1910 | 483,700,000  | 425,100,000                    | .83                                    |
| 1915 | 722,989,000  | 547,802,000                    | .74                                    |

\* Figures not absolutely comparable because of changes in classes of articles included especially in 1890 and 1900.

Our exports of chemicals to our neighbors at the South are rapidly increasing. Exports of chemicals to South America in the fiscal year 1914 (the year immediately preceding the war) showed a total of \$3,106,000; in 1915, \$4,484,000; in 1916 \$10,886,000; and in 1917 \$15,000,000. For the fiscal year 1918 the complete figures are not yet at hand, but it is probable that they will show a total materially greater than that of 1917, and if the increase in chemicals is as rapid as that of other merchandise to South America the total for chemicals in 1918 would approximate \$20,000,000.

#### REVIVAL OF NATURAL DYESTUFF INDUSTRY

A once powerful industry, revived to something of its old proportions by the far-felt effects of the war, is the production of natural dyestuffs. Barred from accustomed supplies by the war's blockade, American color consumers clutched in desperation at any straw promising relief, and the long-dormant natural dye trade was revived. Today the United States is the largest manufacturer of natural dyes in the world, and even after peace has shrunk the present abnormal consumption, the demand for natural dyes should show a permanent increase of from 15 to 25 per cent. The future, then, of the dyestuff industry in this country seems to be full of hope and promise. If we accept our opportunity, and develop our resources with intelligence and wisdom both in legislation and in manufacturing methods, there is no reason why America and not Germany, should not be the dyestuff center of the world.

Since the war cut down England's exports of heavy chemicals there has been a perceptible shift toward New York as the center of gravity of the trade. However, the growth of production and trade in the United States has been rather to supply domestic needs than to build up an international trade. It hardly seems likely that the United States will in any way supersede England as the principal exporter of these products.

#### SULPHURIC ACID, THE BASIC HEAVY CHEMICAL

What may be called the basic heavy chemical, that from which many of the others are manufactured, is sulphuric acid, whose uses, besides the present important one of explosive manufacture, include its employment in the refining of oils and petroleum, the reclaiming of rubber, the preparation of artificial fertilizers,

the manufacture of aniline dyes, and metallurgy. It is also used in making other acids, in the Leblanc process for making soda from salt, and in bleaching.

Under normal conditions a very large proportion of the acid used in industry is manufactured on the spot. The difficulty and danger of handling it in bulk, and the relatively steady demand tend to keep it out of the open market and to minimize its importance in international trade. Germany was the chief country exporting it, shipping annually some 80,000 tons to adjacent European countries. Belgium also exported her surplus. The domestic production of each of the principal consuming countries, however, was far in excess of imports. Table IV gives the approximate production in 1913 of the countries using this acid.

TABLE IV—PRODUCTION OF SULPHURIC ACID

|               | Long Tons |
|---------------|-----------|
| United States | 3,500,000 |
| Germany       | 1,650,000 |
| Great Britain | 1,150,000 |
| Italy         | 640,000   |
| France        | 550,000   |
| Belgium       | 350,000   |
| Russia        | 260,000   |
| Sweden        | 130,000   |
| Japan         | 75,000    |
| Spain         | 16,000    |

The demands of the explosives makers and of the iron and steel industry since the war began have caused a greatly increased production in the belligerent countries, which has meant the investment of large sums in new plants. The United States in 1916 produced 5,642,000 tons, and nearly 7,000,000 tons in 1917. After the war demand ceases it is likely that the efforts of the producers to find a market will cause the acid to become a larger factor in international trade than before.

#### TRADE IN PYRITES AND SULPHUR

The production of sulphuric acid in any country is of course entirely dependent on the supply of the materials from which it is made, principally pyrites and sulphur. It is these which are transported to the point of consumption rather than the acid. The movement of pyrites in 1913 may be seen in Table V.

TABLE V—MOVEMENT OF PYRITES IN 1913

|                    | Production, Tons | Net Imports, Tons | Net Exports, Tons | Consumption, Tons |
|--------------------|------------------|-------------------|-------------------|-------------------|
| Spain and Portugal | 1,283,904        | .....             | 1,200,000         | 84,000            |
| Norway             | 441,291          | .....             | 460,912           | (Very small)      |
| United States      | 341,338          | 848,674           | .....             | 1,190,012         |
| France             | 306,267          | 186,348           | .....             | 492,615           |
| Italy              | 287,727          | .....             | .....             | .....             |
| Germany (1912)     | 258,517          | 1,070,794         | .....             | 1,329,311         |
| Canada             | 141,577          | .....             | 49,000            | 92,000            |
| Russia (1912)      | 123,990          | .....             | .....             | .....             |
| Japan              | 114,387          | .....             | .....             | .....             |
| Hungary            | 104,050          | .....             | .....             | .....             |
| Great Britain      | 11,427           | 794,740           | .....             | 806,167           |

The Spanish supply was the controlling factor in the world's market, and led the price movements. It is in the hands of a number of native mine-owners and is of the most desirable quality. The largest part of it went to Germany and Holland, with the United States next as buyer. Great Britain and France also took large quantities. The Norwegian pyrites went chiefly to Germany. The war, although greatly stimulating the demand for pyrites, at the same time has cut off from the rest of the world one of the largest purchasers—Germany. The scarcity of ships and the high freights on such a bulky material have tended to encourage consuming countries to develop their own supplies rather than to depend on imports. Germany has undoubtedly been hard put to it to replace the loss of the Spanish

supply. Great Britain, being practically without domestic supplies, has imported Spanish pyrites in increased quantity. Her total imports in 1916 were 951,206 tons. The United States similarly took larger quantities of the Spanish ore, 854,432 tons in 1914, 747,027 in 1915, and 1,117,968 in 1916. Early in 1917 however, owing largely to the German submarine warfare, the shipments to this country of Spanish pyrites stopped, and have only recently been resumed. The domestic production in the United States had been steadily growing through the opening of new mines.

The world's trade in sulphur, which normally is used chiefly in the manufacture of paper pulp, has been shifted. It forms a larger item of trade than the manufactured pulp, and is mined in comparatively few places. Table VI gives the total movement of sulphur in 1913.

TABLE VI—MOVEMENT OF SULPHUR IN 1913

|                  | Production,<br>Tons | Net Imports,<br>Tons | Net Exports,<br>Tons | Consumption,<br>Tons |
|------------------|---------------------|----------------------|----------------------|----------------------|
| Italy and Sicily | 413,727             |                      | 414,717              | (Small)              |
| United States    | 311,640             |                      | 67,101               | 244,539              |
| Japan            | 65,467              |                      | 11,650               | 53,817               |
| Spain            | 62,653              |                      |                      |                      |
| New Zealand      | 12,000              |                      |                      |                      |
| Austria          | 10,564              |                      |                      |                      |
| Chile            | 4,400               | 38,142               |                      | 48,703               |
| Canada           |                     | 32,984               |                      | 4,400                |
| Germany          | 1,251               | 43,265               |                      | 32,984               |
| Great Britain    |                     | 18,519               |                      | 44,516               |
| Sweden           |                     | 39,715               |                      | 18,518               |
|                  |                     |                      |                      | 39,715               |

#### GERMANY DOMINATED WORLD MARKET FOR BLEACHING MATERIALS

Another group of heavy chemicals upon which the war has had a considerable effect is that of the various bleaching materials, which are all-important to the textile trade. The world's production of bleaching powder is estimated at 500,000 tons a year. It was obtained chiefly from England and Germany. England, besides producing very large quantities for her own industries, exported in 1913 some 36,319 tons of the material, of which 27,362 came to the United States. England also supplied the distant markets such as India, China, South America, and numerous other countries. In most of the world market, however, especially in Europe, the German product had attained a dominating position. The growth of the electrolytic manufacture of caustic potash from the abundant potash deposits of Stassfurt, in which chlorine is a by-product, had made possible the production of bleaches at a very low cost, in a quantity far in excess of home requirements. The exports in 1912 were 32,254 tons, of which the United States as principal buyer took 9574 tons. France also manufactured a small exportable surplus, in addition to supplying her own extensive textile industries. Bleaching powder was not made commercially outside of Europe until the opening of the electrolytic works at Niagara Falls in 1900. Since then the American output has increased rapidly, although not keeping pace with consumption. The United States consumption in 1913 was about 57,600 tons, of which the domestic production supplied only 19,600 tons.

The war of course completely removed German bleaches from the market, and also cut down British exports considerably, owing to domestic scarcity. In their place American and Japanese bleaching powders have appeared. The electrolysis of common salt in the United States has been largely instrumental in increasing the supply. Demands poured in from foreign buyers, and the United States has become an important exporter of this product.

#### UNITED STATES WILL BE SELF-SUPPORTING IN BLEACHING MATERIALS

The return of peace will find the United States, formerly the principal buyer of bleaches, quite self-supporting. It is a question, however, whether the American product will be able to compete abroad with the cheap British and German product.

The consumption of bleaching powder during the past few years has been affected by the extended use of liquid chlorine which was formerly produced only in Europe, chiefly in Germany, but which is now manufactured here in large quantities and finds an extensive use in reclaiming scrap metal as well as in bleaching. Sodium peroxide, also much in demand as a bleach, is now made at Niagara Falls, replacing the European imports. Caustic soda, which is produced at the same time with chlorine in certain processes and is used in any number of industries—soap making, the manufacture of paper pulp, the mercerizing of cotton, the purification of mineral oils etc.—was obtained from England before the war chiefly. Germany specialized more in caustic potash and did not compete directly. The war has cut down British exports from 75,000 tons to a very small figure, and as in other lines the United States and Japan have partly taken the place. The impossibility of obtaining soda in the usual markets has caused a foreign demand here that has taken up all that the producers could spare.

A similar situation exists in the case of the carbonates and soda ash. England is normally the chief factor in the world markets, exporting some 200,000 tons a year. British exports have kept up well since the war began, but nevertheless the United States has found it profitable to export these products where they were imported before the war.

In the cyanides, essential to metallurgy, and the chromates and sulphates (saltcake), Germany formerly controlled the market, England being second. The United States was a large buyer of cyanide, but recently the Niagara Falls works have produced large quantities.

#### DISLOCATION IN FERTILIZER MOVEMENTS

In the field of fertilizers, in which the largest international movements of chemicals took place before the war, the dislocation has been large. Potash, over 90 per cent of which is used for fertilizers, has been most affected, as Germany is practically the sole source. The Stassfurt mines, operated by German capital, are united in a close cartel or monopoly of which the German government is a member, which fixes the output, handles all sales throughout the world, divides it into portions for domestic use and export, and fixes wholesale prices. Owing to the complete monopoly, prices have always been entirely artificial and yielded large profits.

The United States was by far the largest consumer outside of Germany herself. The efforts to produce potash here from Western alkali lakes, alunite, and Pacific kelp, although aided by government appropriation and stimulated by the high prices since the cessation of imports from Germany, have had small results compared to the normal consumption. Foreign sources, such as those near Barcelona, Spain, have not been more successful. The German mines, on the other hand, although cut off from most of their outside markets,

have been kept running by war demands at home, producing 904,000 tons in 1914; in 1915, 680,000 tons; and in 1916, 714,000 tons. In view of the fact that prices could be considerably lowered from their pre-war level without jeopardizing profits, there seems so far little likelihood that the German monopoly will be less secure when peace is signed. The substitutes that have been developed, however, will undoubtedly affect consumption in industries other than the fertilizer. Potash salts are used to a great extent in making soap, fireworks and glass. The substitution of soda compounds for potash in making glass, which has been very successfully carried out, will come near making the world independent of German glass. A similar substitution is proving a success in soap making. Potash explosives are not made now to any great extent outside of Germany.

#### NITRATES, NATURAL AND ARTIFICIAL

The recent action by the Government of the United States for the establishment of works for the production by artificial process of the nitrates for which the United States has been heretofore dependent upon the supplies imported from the great nitrate beds of Chile, calls attention to the wonderful development, especially since the beginning of the war, in the art of obtaining nitrate from the air.

In the five years preceding the war Germany imported an annual average of 700,000 tons of nitrate of soda from Chile, France about 350,000, Belgium for herself and neighbors about 350,000, Great Britain 150,000, the remainder of Europe about 300,000 tons, and the United States about 500,000. While some of this was used for the production of explosives, especially by Germany and France, and also limited quantities for the production of nitric acid for chemical industries, a very large proportion was used in times of peace as soil food.

Practically all of the nitrate supplies of the world have in the past come from Chile, whose exportations have in recent years averaged about 2,400,000 tons per annum, and the importations of Europe and the United States have as above noted aggregated about 2,300,000 tons per annum in the five years preceding the war. With the opening of the war all of the great importers of nitrates, Germany, France, the United Kingdom and the United States, realized the importance of greatly increasing their nitrate supplies for use in manufacturing war material as well as a continuation of its use for soil food.

The quantity of nitric acid required by the United States Government for its own uses in the manufacture of explosives is estimated at 20,000 tons per annum in times of peace, and in time of war 180,000 tons, while that of the other countries may be measured by the fact that Germany has increased the product of the nitric acid-producing materials to an equivalent of 100,000 short tons in 1915 and 320,000 in 1917.

#### SUMMARY OF PROGRESS SINCE 1914

In summarizing the progress in the chemical industries since 1914 it is interesting to note that we are exporting dyes and chemicals to Germany's old clients. For instance in 1917 we sent Spain \$3,192,000 worth of dyes, as against a total which was not important

enough to enumerate in Government statistics in 1914. France took \$1,404,576 worth against \$49,000 in 1915 and less than that in 1914. Mexico took \$576,000 worth in 1917 against \$2,000 worth in 1915, Argentina \$423,000 against \$32,000, and Brazil \$1,395,000 compared with \$11,000. British India imported from us \$1,237,000 worth compared with \$11,000 in 1915.

Before the war 90 per cent of the artificial dyes and colors were imported, five or six concerns with 400 operatives producing 3300 short tons per year. Now there are over 100 enterprises, each making special colors and over 100 concerns making crudes and intermediates. Sulphuric acid has doubled in production. In 1916, 6,250,000 tons of 50 degree Baumé were produced. The estimate for 1917 is much greater and the production for 1918 will again greatly increase. Gasoline production has increased from 35,000,000 to 70,000,000 barrels per annum since 1914. The production of explosives and consequent consumption of nitric acid has increased enormously. The smelting of all metals, iron, zinc, copper, antimony, tin, mercury etc., and the production of their alloys, has increased to meet the country's needs. Potash importation from Germany was stopped by the war and its production in this country in 1917 was over 28,000 short tons. By-product coking doubled its capacity in the last three years. Light oil, which contains the benzene and toluene needed for explosives, jumped from 7,500,000 gallons in 1914 to 60,000,000 gallons in 1917 and is again being largely increased. Ammonia production has increased 100 per cent in three years and the visible supply is insufficient to meet the demands. From these facts it is easy to realize that the growth of the chemical industries in the United States since 1914 has been phenomenal. Not only have factories sprung up to manufacture products formerly imported, but great expansion has taken place to supply the increased demand for all chemical products. The country now manufactures practically everything required along chemical lines. These are but a few instances of our chemical progress, but they show that we can go forward with every confidence of no serious shortage of the many chemical products required for domestic consumption or foreign export.

#### Five-Hundred-Ton Government Powder Plant at Nashville

This plant is being built in nine units—each one complete in itself. One of these units is approximately eight times the size of the largest smokeless powder plant in the United States prior to 1914. The entire plant is 70 times as large as the largest plant before the war. It covers an area one and one-half miles wide by three miles long. To operate it at capacity will require 1,500,000 pounds of nitrate of soda per day—675,000 pounds of sulphur per day. It will consume 4500 tons of coal for each 24 hours, which is equivalent to 100 carloads, or two trainloads. It will require 100,000,000 gallons of water per 24 hours, or as much water as is used by a city having a population of one million people. The central power plant will contain 68 boilers, each with a rating of 825 horsepower. It will be the largest smokeless powder plant in the world and the last word in powder making. It will require 20 to 25 thousand men ten to twelve months to complete it.

# Statistics of Chemical Imports in Preparation

The American Chemical Society Adopts Comprehensive Plan to Give the Chemical Industry Vital Information Regarding This Country's Chemical Dependence

THE Council of the American Chemical Society took no more important action at the recent Cleveland meeting than its adoption of the report of the committee cooperating with the Bureau of Foreign & Domestic Commerce in obtaining statistics on chemical imports for the fiscal year 1913-1914. The recommendations of the committee call for the appointment of a permanent Committee on Import Statistics, comprising the editor of the *Journal of Industrial & Engineering Chemistry* and the vice-president of the American Chemical Society. The plan of action will result in giving us for the first time an intelligent comprehension of our chemical dependence as well as a basis for building wisely in the future.

A great deal has been said in general terms during the past few years about our chemical dependence on foreign countries, particularly Germany. To a certain extent this has been true, although it is possible that the real facts have been exaggerated. In any event there was but one way to ascertain the real extent of our dependence, and that was to analyze the invoices of imported chemicals, raw or finished, in the Bureau of Foreign & Domestic Commerce, and list the items therein contained. In this way alone would it be possible to arrive at information which was essential to any intelligent efforts to build up the chemical industry in this country.

Largely through the efforts of Dr. B. C. Hesse, who has been the leading spirit in this matter for the American Chemical Society, and the cooperation of Dr. E. R. Pickrell of the U. S. Appraisers' Stores of the Port of New York, the laborious task of reviewing the invoices of the Bureau of Foreign & Domestic Commerce has been under way for some time past and promises to be completed by December 1, 1918. An idea of the extent of the work involved can be gained from the fact that upward of 20,000 invoices of imported chemicals has to be segregated from a total of more than 500,000 general invoices from all ports of entry. From these 20,000 invoices it was then necessary to transcribe the individual items, which will amount to more than 4000.

The information which will be gained regarding these 4000 items will comprise:

1. The name of the chemical, or material for the chemical industry.
2. The total quantity imported, expressed in pounds or other units.
3. The total value, expressed in dollars.
4. The countries of origin, arranged in the order of their participation, and showing the percentage of such participation.

It is expected that this information will fill a book of about 300 pages, which will be issued about February 1, 1919, and sold to the public at 30 cents per copy. Here, then, we will have the true story of our chemical dependence in 1913-1914, the last normal year before

the war. We will know what we imported, and how much; what it was worth and where it came from. With these facts at hand we should be able to determine the possibility of independence and whether it is worth striving for. In some items the game may not be worth the candle, or we may not have the requisite raw materials in this country. In such an event our manufacturers will be well advised to dismiss any thought of engaging in their production.

## COÖPERATION OF GOVERNMENTAL AGENCIES

But in the conception of Dr. Hesse's committee it will not do to stop with this information, for still more important and valuable data are to be obtained by elucidating these statistics. He recommends that the American Chemical Society classify the 4000 or more items of import into groups showing their mineral, animal or vegetable origin. Having done this he would seek the cooperation of governmental agencies in ascertaining foreign and domestic resources of these materials. It requires no stretch of the imagination to discern the far-reaching influence of such a plan. The Geological Survey, for example could prepare a concise statement of the world's resources of the items of mineral origin. This would show whether or not we have a domestic source of supply of a given material that would support local manufacture in case someone undertook it. It would show our resources and deficiencies, and suggest to the Survey the most profitable lines of search for minerals. Similarly the Department of Agriculture would cooperate on the items of animal and vegetable origin. There would remain then, to complete our economic knowledge of these 4000 items of import, only a statement of the industrial and commercial uses of the materials. And we understand that the Tariff Commission has been approached on this score, with the prospect of securing the desired cooperation.

## A PERMANENT COMMITTEE CHARGED WITH RESPONSIBILITY

When the foregoing is an accomplished fact we will know the extent of our dependence on foreign countries. When that is known it will be time to compile similar statistics and data on our chemical exports and our domestic production. The achievement of these ends will leave little to be desired for the intelligent direction of our chemical industry. But in order to accomplish the purpose it is necessary that some permanent body be charged with responsibility for the results and vested with the requisite authority to produce them. Hence the committee's recommendation that two officials of the American Chemical Society be charged with this duty. The committee is properly small—two, with power to add to their number and invite cooperation from other societies. The service to the industry is worthy of the American Chemical Society, and we look to see an early and satisfactory performance of duty.

## War Disturbances and Peace Readjustments in the Chemical Industries\*

A Bird's-Eye View of the Dislocations of Normal Trade and Industry Caused by the War—Expansion for War Needs—New Uses Must be Discovered for Chemicals Now Devoted to War Purposes

By GRINNELL JONES

Chemist to the United States Tariff Commission

WHEN peace is restored the competitive strength of the nations in all industries will have been profoundly altered. Chemistry and machinery have played a larger part in this war than in any previous war, and therefore the greatest changes may be expected in the metal working and in the chemical industries. Moreover, our new American cargo ships will make us more than ever interested in foreign trade. The Tariff Commission is actively studying these war disturbances in order to assist in the readjustment and reconstruction that must follow when peace comes.

Among the chemical industries, the first to feel the stimulus of war was the explosive industry. The expansion of American smokeless powder plants was sufficient to prevent a German victory in France and Russia in 1915. It is not revealing military secrets to say that there has been some growth since 1915. We all hope that the peace terms will be so satisfactory that the military explosive plants themselves will no longer be needed. Nevertheless, there will be a permanent increase in the competitive strength of the American chemical industries through the growth of the subsidiary industries which now supply the raw materials to the explosive industry.

### SULPHURIC ACID PRODUCTION DOUBLED

Our production of sulphuric acid is at least twice what it was before the war. The growth has been largely in contact acid, and therefore when the demand for explosives disappears, the American chemical industries will have available large supplies of pure and concentrated sulphuric acid. Moreover, the growth of the acid industry has been made possible by a great increase in the production of American sulphur and by a smaller although significant increase in the mining of pyrites.

The nitric acid industry has grown relatively more than the sulphuric acid industry. The output of nitric acid from Chilean niter is now more than ten times as great as it was before the war.

The significance of this growth of the sulphuric and the nitric acid industries to our dynamite, dyestuff, and pyroxylin plastic industries need not be emphasized here.

### SYNTHETIC AMMONIA AND NITRIC ACID

Of greater significance than this stimulus to industries already well established has been the birth of new industries. We have a new synthetic ammonia and nitric acid industry. Plants have been built and, during the war at least, will be operated by the Government.

When the full story of these plants can be told, it will reveal that American chemists have, under the pressure of war needs, been able to devise substantial improvements upon the Haber and Ostwald processes developed by the Germans before the war. These processes were the result of nearly two decades of work on these problems as a part of their military preparedness. It is not improbable that after the war nitric acid made from synthetic ammonia may prove to be cheaper than nitric acid made from Chilean niter. In any case American agriculture will assuredly have a new large source of nitrogeous fertilizer materials.

### LARGE SUPPLIES OF BENZOL AND TOLUOL AFTER THE WAR

In 1914 our production of crude light oil would have been sufficient for the production of only about 4,500,000 gallons of benzol and of about 1,500,000 gallons of toluol, and only a part of which was distilled. As is shown in our forthcoming report on the production of American dyes and coal tar chemicals, in 1917 our output of benzol was 40,200,000 gallons, and of toluol was 10,200,000 gallons. In 1918 further substantial growth is to be expected through the installation of stripping plants at city gas works. The toluol is now going almost entirely into explosives as is also a considerable fraction of the benzol. When the demand for explosives disappears, it is to be expected that the prices of benzol and toluol will drop to the point where it will be profitable to add them to gasoline for motor fuel. A similar condition will probably exist abroad and, since America has the greatest known natural resources for the production of gasoline, benzol and toluol should be as cheap or cheaper here than abroad. Therefore the industries consuming benzol and toluol may be assured of ample supplies of these materials at favorable prices.

### SYNTHETIC PHENOL AND MONOCHLOROBENZOL ARE WAR BABIES

Before the war we had no synthetic phenol industry, whereas in 1917, as is shown in our forthcoming report, 15 plants produced 64,146,499 pounds of phenol valued at \$23,715,805, most of which was used in making picric acid. If this new industry is to survive, there must be a greater consumption of phenol in the industries for peaceful purposes. Fortunately, phenol is used as an intermediate in the manufacture of some representatives of every class of finished coal-tar chemical products including dyes and lakes, photographic developers, medicinals, flavors, perfume materials, synthetic resins, synthetic tanning materials and explosives. Leaders in the chemical industries are already making plans for

\*An address delivered at the meeting of the American Chemical Society in Cleveland, September 10.

the industrial development of the uses of phenol when the phenol is no longer needed for explosives.

Another war baby is monochlorobenzol, which was made during 1917 by eight American firms, with an output of nearly twenty-five million pounds, valued at a little less than five million dollars. The dye industry will use a part of this productive capacity permanently, but new discoveries by American chemists will probably be needed to utilize the total productive capacity. Incidentally, this product furnishes a new outlet for chlorine, a new by-product source of muriatic acid and raises a new problem in the utilization of dichlorobenzol, an unavoidable byproduct.

Before the war there was but one producer of aniline oil in the United States. In 1917 there were twenty-three producers with an output of 28,806,524 pounds, valued at \$6,758,535. As only a relatively small proportion of this substance goes into explosives, the peace readjustments will not be complicated by a collapse of a military demand, but will depend primarily on the competitive strength of the American industry.

The war has also stimulated the production of mercury for the manufacture of fulminates. The American production has about doubled since the beginning of the war. Formerly we had a balance of imports; now we have a larger balance of exports.

#### INFLUENCE OF GAS WARFARE ON CHEMICAL INDUSTRY

Poison-gas warfare is also destined to have a permanent influence in the chemical industries. Although there is no reason to expect that uses will be found for phosgene and mustard gas on a scale approaching the present and prospective military use, the plants erected for their manufacture need not prove a total loss when the military demand ceases. Nearly all of the noxious substances used in poison-gas warfare require chlorine for their manufacture, and an increase in the production of chlorine in the United States is therefore certain. There is much hope that some of the substances produced as intermediate steps in the manufacture of the poison gases may be utilized for purposes other than warfare, but these are matters not yet to be discussed. Phosgene, except for the dangers attending its use, is an excellent reagent for many processes involving chlorination or dehydration and for making Niehler's ketone. Fortunately, the risk in using phosgene is greatly minimized by the development of the new gas mask. The intensive work which hundreds of American chemists have been and are doing to improve the design of the gas mask will undoubtedly prove a blessing to workmen exposed to noxious fumes in chemical factories throughout the world when peace is restored.

#### ACETONE, ACETIC ACID AND BUTYL ALCOHOL

Still another industry which has been stimulated by a direct war demand, is the manufacture of acetone, which is used as a gelatinizing agent in the manufacture of the explosive, cordite; as a solvent for airplane dopes; and in the manufacture of poison gases. Before the war, acetone was obtained entirely as one of the products of the wood distillation industry, but there are now at least four new processes in commercial operation in the United States or Canada for the manufacture of acetone.

It has been found that glucose can be fermented by

a suitable organism to give acetone directly. Butyl alcohol is a byproduct of this fermentation, and becomes commercially available in appreciable amounts. The development of uses for butyl alcohol is an attractive problem.

The other processes for making acetone produce acetic acid or an acetate as an intermediate step, and may therefore permanently affect the acetic acid industry. The most obvious and perhaps the simplest of these processes depends on fermenting molasses to alcohol, which is then converted into acetic acid by the rapid vinegar process. The conversion of acetic acid into acetone in an old and well known process, but the details have been improved.

Another process depends on making acetylene from calcium carbide. By the aid of a suitable catalyst, the acetylene is made to combine with water yielding acetaldehyde which may be readily oxidized to acetic acid. Still another process depends on fermenting ~~acetone~~ under such conditions that sodium acetate and potassium salts are secured.

The war has stimulated the production of many other products, a few of which may be briefly mentioned: castor oil for lubricating airplane motors; phosphorus for incendiary bombs; barium and strontium nitrates for signal rockets. The output of soda ash has increased by 68 per cent since 1914, and the output of caustic soda has more than doubled.

#### CURTAILMENT OF IMPORTS AFFECTS DYE INDUSTRY

New conditions in the chemical industries have also been created by the curtailment of imports. As a direct consequence of this stoppage of imports from Germany a new American dye industry has been established. It is true that some dyes were being made in the United States before the war, but the makers relied on Germany for the necessary intermediates, with the exception of a small amount of aniline made here by a single producer. During 1917, 134 different intermediates were made by 118 firms. One firm made 53 different intermediates. Dyes were made by 81 firms. The total production of dyes in the United States during 1917 was approximately equal in gross weight to the annual importations before the war. The exports of American dyes exceeded in value, although not in quantity or variety, our imports before the war. The dye industry is not dependent on any imported raw material except sodium nitrate from Chile. Many important dyes are still lacking, but indigo and alizarin are now on the market in significant amounts, and the vat dyes for cotton derived from anthracene are coming.

A new potash industry has also arisen, but its future does not seem so promising as the future of the new dye industry. Here Germany has an inherent geological and geographical advantage. Although shipments from Germany ceased early in 1915 and although prices have advanced to about ten times the pre-war prices, the American production during 1917 was only about 13 per cent of our pre-war consumption. This relatively small production was obtained from many sources and by many processes. There is an excellent prospect that the recovery of potash as a byproduct of cement mills will survive German competition and ultimately supply about one-third of our needs. In addition, significant amounts will probably be secured as a byproduct of the pig-iron

blast furnace. That the other branches of the potash industry can survive German competition is open to serious question.

#### UTILIZING SHIPPING CAPACITY TO BEST ADVANTAGE

Within a few months after the outbreak of the war, imports to the United States from Germany and her allies came to an end. As the months went by, it became increasingly difficult to obtain cargo space for imports from any part of the world. Now the limiting factor in the American participation in the war is shipping for our troops and their supplies, and therefore ships are no longer free to seek the most profitable cargo and route, but are being assigned to routes and cargoes by the Shipping Board on the basis of military needs rather than profits. The Shipping Board has organized a Division of Planning and Statistics, which is making a study of world commerce and the military and civil requirements, for the purpose of utilizing available shipping in a way that will contribute most to the winning of the war. Military requirements make it essential that an abnormally large proportion of the world's shipping shall be used in the North Atlantic. This has made it necessary to curtail imports from other parts of the world to essential requirements.

W. B. D. Penniman of Baltimore is the chemist on the Staff of the Shipping Board. He must decide what chemicals need not be imported at all, and the amounts of others which must be imported to supply essential needs. The importance of this work can perhaps best be made clear by an example. The Shipping Board, after consultation with the Food Administration, decided that ships could not be spared for the importation of tapioca from Java and the Straits Settlements. The War Trade Board accordingly announced that licenses for the importation of tapioca would not be granted. Efforts were immediately made to secure a modification of this order on behalf of manufacturers of nitro-starch for the Army, and on behalf of manufacturers of mucilage for the Post Office Department. Nitro-starch which, in the United States at least, was hardly beyond the experimental stage at the outbreak of the war, has been improved until it is now one of the safest of all explosives to handle and finds important military uses. Until a few months ago it was made from tapioca. Penniman, however, succeeded in convincing the officers of the War Department and the manufacturers that a satisfactory product could be made from corn-starch.

The details of the manufacture have been worked out cooperatively by the starch producers, the manufacturers of nitro-starch and the experts of the War Department with such success that nitro-starch from corn is not only better but more economically produced than nitro-starch from tapioca. The Post Office Department also readily agreed to use some locally available material instead of tapioca for mucilage on stamps. The shipping saved on this one item of tapioca for nitro-starch is sufficient to transport and sustain in France more than twenty-five thousand fighting men. Mr. Penniman's services to the nation on questions of this character deserves to be better known and appreciated. Imported materials for the time being should be used with the utmost economy and only for essential needs. American chemists can render valuable public service by find-

ing substitutes for materials which must be imported from overseas.

It seems probable that many of the discoveries in regard to the use of substitutes for imported materials made under this pressure of war needs will prove of permanent value and have a permanent influence on international trade.

#### DISLOCATIONS IN THE FERTILIZER INDUSTRY

A third source of war disturbances in the chemical industry has been due to the diversion of materials from their customary use to war uses. The fertilizer industry has probably made the greatest sacrifices of this sort. Sodium nitrate and ammonia are required for the manufacture of explosives in such large quantities that the amount left for use in fertilizers has been and will be much reduced. Raw phosphate rock has of course been plentiful but the acid used in the manufacture of acid phosphate has been largely diverted to making explosives. The relatively small supplies of potash have been very high in price and normal amounts have not been available at any price. The peace readjustments may however be expected to bring compensation to the fertilizer industry. Large new supplies of nitrogenous fertilizer materials will be available from the new nitrogen fixation plants. The new and enlarged sulphuric acid plants must again find the chief outlet for their product in the making of fertilizers. Finally, the German monopoly of the potash market is likely to be broken through the French control of Alsace and the new developments in America and Spain when peace comes. It is therefore reasonable to expect a large increase in the manufacture and use of fertilizers with a resulting benefit to all producers and consumers of food.

Chlorine also is likely to be diverted from its normal uses to the manufacture of poisonous gases to a considerable extent. In spite of the erection of new plants it is quite probable that we may all be asked to use paper lacking in the whiteness to which we have been accustomed.

Chemists in industries using chlorine should prepare to facilitate this diversion now, and plan to use more chlorine later when the military demand ceases.

It is evident that the *status quo ante* cannot be re-established in the chemical industries any more than it can be re-established in international relations. Peace will bring new conditions of international competition and radical readjustments in industry from a war basis to a peace basis.

The Tariff Commission is endeavoring to secure and have ready for immediate use all information likely to be helpful to Congress in determining the part which the tariff is to play in these readjustments. We desire information in regard to the industrial development and technical progress of industries throughout the world; in regard to the sources of their raw materials and the uses of their products, and in regard to any changes in conditions likely to have a permanent influence on costs of production, or the competitive strength of industries here and abroad. The assistance and coöperation of manufacturers, importers and consumers in the collection and interpretation of the information mentioned is desired.

Washington, D. C.

| TABLE A.—GROWTH OF AMERICAN CHEMICAL INDUSTRIES 1909 TO 1914 |                                                                                                                                                                                        |                  |                              |               |                                  |                              |                                                        |      |                                                                              |

|                               | 1904                | 9,826                                      | 227,326                                | 1,388,328    | 102,388     | 635,919              | 1,075,191            | 441,600                               |
|                               | 1899                | 8,928                                      | 196,538                                | 1,163,816    | 77,560      | 451,457              | 761,691              | 310,234                               |

The 344 industries distinguished in the census of 1914 have been grouped into 14 general classes in order to facilitate comparison of one broad type with another. In Table 6 are given the figures for "all industries" and the group of "chemicals and allied products" for four census periods. In general the reader will observe in the chemical group a marked difference between the figures of the first two and last two periods, showing increases in the latter of 50 to 100 per cent or more. Thus, the number of establishments increased from 8928 in 1899 to 12,374 in 1914. Capital invested in-

facturing, if any, done in educational, eleemosynary and penal institutions.

#### BAKING POWDERS AND YEAST

This classification includes various compounds for raising bread, cake, and pastry, and dry, compressed, and liquid yeast. Table 106 shows separate statistics for the establishments whose chief product was baking powders and for those making yeast as the product of chief value. Many minor products were reported by the manufacturers of baking powder, such as bluing,

TABLE 106

| Industry                                              | Number of Establishments | Wage Earners (Average Number) | Chemicals and Allied Products: 1914 |           |                   |                   | Value Added by Manufacture |
|-------------------------------------------------------|--------------------------|-------------------------------|-------------------------------------|-----------|-------------------|-------------------|----------------------------|

| Varnishes.                                            | 215                      | 2,734                         | 29,861                              | 1,865     | 16,878            | 33,215            | 16,337                     |
| Tar, pitch, rosin                                     | 176                      | 25,366                        | 325,646                             | 19,397    | 325,265           | 396,361           | 71,096                     |
| Salt                                                  | 98                       | 5,089                         | 33,151                              | 3,041     | 6,273             | 14,070            | 7,797                      |
| Soap                                                  | 371                      | 14,172                        | 92,872                              | 8,088     | 88,867            | 122,942           | 39,075                     |
| Turpentine and rosin                                  | 1,394                    | 34,817                        | 20,745                              | 8,583     | 5,536             | 20,990            | 15,454                     |
| Wood distillation, not including turpentine and rosin | 95                       | 2,782                         | 17,563                              | 1,565     | 6,496             | 9,882             | 3,386                      |

creased more than 100 per cent; cost of materials nearly 300 per cent; value of products nearly 300 per cent; and value added by manufacture over 200 per cent.

#### SCOPE OF THE CENSUS

As might easily be imagined, the officials in charge of the census are somewhat puzzled as to just what industries should be grouped in chemicals and allied products. Of necessity the decision must be more or less arbitrary, and as shown in Table 106 the group includes "not only the industries whose products are chemicals in the ordinary sense of that term, but also the industries which employ to a large extent chemical processes of manufacture." Table 106, in effect, is a detailed analysis of the summary figures for 1914 given in Table 6. The census did not cover establishments which were idle during the year or those which had a value of products of less than \$500; nor did it cover the manu-

facturing, chocolate, coffee, spice, confectionery, flavoring extracts, food preparations, and vinegar; while those making yeast also reported stock feed and alcohol.

In addition to the products covered by Table 106 baking powders to the value of \$1,867,674 were reported in 1914 as made for sale by establishments assigned to other industries, principally those grinding and roasting coffee and those manufacturing flavoring extracts. Yeast to the value of \$2,451,410 was reported as sold by distillers and manufacturers of vinegar. In 1909 baking powders and yeast to the value of \$3,963,573 were reported by establishments assigned to other industries. Many concerns make similar products for their own consumption in further processes of manufacture.

#### BLACKING, STAINS, AND DRESSINGS

Establishments in this industry manufacture principally blackings, waxes, stains, dressings, and polishes

for leather boots and shoes, harness and belting, stove polish, burnishing inks, and enameled carriage-top dressings, as well as pastes, washes, dyes, and gums.

In addition to the products covered by Table 106 blackings, stains and dressings to the value of \$377,617 in 1914 were reported by establishments assigned to other classifications, principally "mucilage and paste," "paints," "patent medicines and compounds," and "leather, tanned, curried, and finished."

#### BLUING

Establishments under this classification manufacture principally laundry bluing, soluble or liquid, aniline blue etc. The usual materials used in this manufacture are indigo and Prussian blue.

In addition to the products covered by Table 106 bluing to the value of \$269,199 in 1914 and of \$350,377 in 1909 was reported by establishments assigned to other classifications, principally "pickles, preserves, and sauces," "flavoring extracts," "patent medicines and compounds," and "coffee and spice, roasting and grinding."

#### BONE, CARBON AND LAMPBLACK

Establishments in this classification are engaged in the preparation of black pigments. There are three principal methods: The carbonization of bones in retorts, producing bone black or animal charcoal, also known technically as "char"; the deposition of carbon black by the imperfect combustion of natural gas, the flame impinging upon slate or metallic slabs or revolving cylinders; and the deposition of lampblack by the incomplete combustion of coal tar, wood tar, petroleum, rosin etc., the dense smoke depositing the soot in chambers. Some establishments make ivory black by the carbonization of scraps of animal teeth and tusks.

Table 106 shows statistics for "bone black and lampblack" and for "carbon black" separately, each establishment being classified according to its product of chief value. Table 107 presents the statistics of the production of bone black, carbon black, and lampblack by establishments in all industries for 1914 and 1909.

| TABLE 107                           | Bone, Carbon and Lamp Black |             |
|-------------------------------------|-----------------------------|-------------|
|                                     | 1914                        | 1909        |
| Total number of establishments..... | 39                          | 57          |
| Total value of products.....        | \$2,953,947                 | \$2,135,554 |
| Products                            |                             |             |
| Bone black (animal charcoal):       |                             |             |
| Number of establishments.....       | 7                           | 7           |
| Pounds.....                         | 44,509,000                  |             |
| Value.....                          | \$1,332,000                 | \$1,070,333 |
| Carbon black:                       |                             |             |
| Number of establishments.....       | 20                          | 18          |
| Pounds.....                         | 22,869,000                  |             |
| Value.....                          | \$916,091                   | \$625,514   |
| Lampblack:                          |                             |             |
| Number of establishments.....       | 12                          | 32          |
| Value.....                          | \$503,856                   | \$439,707   |

<sup>1</sup> Includes \$215,212 the value of 4,786,394 pounds, and \$288,644 for which no quantity was reported

#### CANDLES

The principal products of establishments under this classification are candles of all descriptions made of tallow, paraffin, stearin, and wax. In addition to the products covered by Table 106 candles were reported in 1914 by petroleum refineries to the value of \$1,402,945 and by soap manufacturers to the value of \$150,492, while establishments assigned to other classifications, principally chemicals, reported candles to the value of \$411,631. The candles made by petroleum refineries were

not reported separately in 1909, and the amount cannot be stated, but candles to the value of \$527,910 were reported by establishments engaged primarily in the manufacture of "soap," "chemicals" and "oil, not elsewhere specified."

#### CHEMICALS AND ACIDS

Prior to the census of 1904 the general statistics for chemicals, sulphuric, nitric, and mixed acids, and wood distillation were included under the single classification of "Chemicals." For the censuses of 1904, 1909, and 1914, the three have been shown separately and a segregation of data made for 1899 for comparison. The statistics for wood distillation products are given in Table 122.

TABLE 122

| WOOD DISTILLATION                                        |  | 1914          | 1909             |
|----------------------------------------------------------|--|---------------|------------------|
| Number of establishments.....                            |  | 101           | 136              |
| Wood distillation industry.....                          |  | 95            | 120              |
| Manufacturing subsidiary wood distillation products..... |  | 6             | 16               |
| Number producing crude alcohol.....                      |  | 80            | 98               |
| Number producing refined alcohol.....                    |  | 16            | 17               |
| Number distilling pine wood.....                         |  | 15            | 33               |
| Wood, cords.....                                         |  | 1,042,517     | \$1,265,157      |
| Hardwoods.....                                           |  | 970,308       | 1,149,847        |
| Pine.....                                                |  | 72,209        | 115,310          |
| Crude wood alcohol.....                                  |  |               |                  |
| Consumed, gallons.....                                   |  | 7,388,902     | 9,670,497        |
| Purchased—                                               |  |               |                  |
| Gallons.....                                             |  | 5,565,446     | 7,135,464        |
| Cost.....                                                |  | \$1,408,124   | \$1,784,023      |
| Made and consumed, gallons.....                          |  | 1,823,456     | 2,534,889        |
| Products.....                                            |  |               |                  |

<sup>1</sup> Forest Products of the United States, 1909, p. 163; includes some wood used in charcoal burning.

<sup>2</sup> Figures not available.

<sup>3</sup> Total production of acetate of lime.

<sup>4</sup> Total production of turpentine and rosin, all industries; turpentine, 27,648,939 gallons; rosin, 2,944,929 barrels.

<sup>5</sup> Total value of products of the charcoal industry and of charcoal made for sale in other industries, \$3,209,628.

<sup>6</sup> Includes acetic acid, acetate of soda, acetone, formaldehyde, pyrolytic iron, and wood ashes. Total production for sale by all industries, of acetone, 10,425,817 pounds, value \$1,090,583; acetic acid, 70,617,637 pounds, value \$1,272,294; formaldehyde, 8,426,247 pounds, value \$655,174.

<sup>7</sup> In some cases equipment was reported as retorts at one census and ovens at another census.

Although the manufacture of sulphuric, nitric, and mixed acids is in the main a specialized industry, there is a considerable production by establishments that also manufacture other chemicals, and a large quantity of sulphuric acid is made in conjunction with the fertilizer industry. Hence, in Table 106, which presents in detail the statistics for materials and products for 1914 in comparison with those for 1909, 1904, and 1899, the statistics for sulphuric, nitric, and mixed acids are included along with those for other acids. At prior censuses establishments engaged in the manufacture of supplies for calcium lights, chiefly lime cylinders, and oxygen gas, constituted a separate industry, but these are now included under chemicals.

The chemical products are classified under 12 groups: (1) acids; (2) sodas and sodium compounds; (3) potash and potassium salts; (4) alums; (5) coal-tar products; (6) cyanides; (7) bleaching materials; (8) chemical substances produced by the aid of electricity, including those belonging under other groups; (9) plastics; (10) compressed or liquified gases; (11) fine chemicals; and (12) chemicals, not otherwise specified, such as glycerin, cream of tartar, epsom salts, blue vitriol, copperas etc.

The schedule used in taking the census named, under the various groups, the chemicals which at prior censuses had been reported by three or more establishments, and provided for the reporting in detail of such other chemicals as were manufactured. In some cases, however, manufacturers did not separately report all products, consequently there results a large amount of unclassified chemicals, which may include a considerable production of some of those for which detail figures are given and undoubtedly include others which could have been shown if they had been separately reported. The production is shown for all chemicals that can be separately given without the disclosure of individual operations, and those separately returned, but which can not be individually given, are named and reported as a whole under the several groups.

Many establishments distilling coal tar consume part of the product in the manufacture of roofing paper, roofing felt etc., and hence are classified as engaged in other industries, and their coal-tar production is not included under Group 5. Except as stated, where the production made and consumed is given, the figures refer to the quantity and value of the product made for sale and do not include that made and consumed in the same plant.

With respect to the group of products produced by the aid of electricity (Group 8) it should be said that many of the electrochemical and electrometallurgical products have, until recent years, been under the protection of patents, and detail statistics of production cannot be given for some of the most important without disclosing the operations of individual establishments.

Under plastics (Group 9) there is included pyroxylin plastics, sold under such trade names as celluloid, fibroloid, viscoloid, pegamoid, pyrolyn, xylonite etc.; pyroxylin or soluble cotton; viscose; artificial silk; phenolic condensation plastics, such as bakelite and condensite; rubber substitutes and all plastics formed by using caoutchouc, gutta-percha, casein, fibrin, gluten, gums, and glue, or other cementing materials by which sawdust, woodpulp, bonedust, zinc oxide, antimony, kaolin,

<sup>1</sup> Figures not available.

<sup>2</sup> Does not include materials used in chemical manufacture by establishments producing chemicals as subsidiary products.

<sup>3</sup> See Note 6.

<sup>4</sup> Includes oleum, in 1914, 60,963 tons; and in 1909, 27,602 tons, converted, above, to 50° acid at 1.71; and sulphur trioxide, in 1914, 1,391 tons; and in 1909 992 tons, converted, above, to 50° acid at 1.93.

\* Includes considerable quantities of the acids for which statistics are given above, notably sulphuric, nitric, mixed, acetic and muriatic acids, which a few establishments reported in lump without classification according to kind.

<sup>1</sup> Includes the following acids, in order named as to value: Tartaric, carbonic, picric, salicylic, lactic, oxalic, hydrofluosilicic, pyrogallic, gallic, pyroglucous, hypophosphorous, benzoic and arsenic.

<sup>2</sup> Number manufacturer, bicarbonate, caustic, salt soda, soda ash or borax in 1914 and 1909; and same not including borax in 1904 and 1899.

<sup>3</sup> Includes the following sodium compounds in order named as to value: Hyposulphite, sesquicarbonate, acetate, nitrate, perchlorate, bromide, iodide, fluoride, bisulphate, citrate, diamide and oxalate.

<sup>1</sup> Includes sodium aluminum sulphate.

<sup>2</sup> Includes 38,342,000 pounds of unclassified alums.

<sup>3</sup> Not including value of 109,901,315 gallons of tar, \$2,867,274, produced by by-product coke ovens; of 125,938,607 gallons of tar, \$3,252,756, produced by gas plants; and of coal-tar dyes and intermediates, \$4,652,947, made largely from stock of foreign origin.

<sup>4</sup> In addition, 1,239,382 pounds of cyanide blues, reported as Prussian blue, valued at \$387,077, were manufactured by 15 establishments engaged primarily in the manufacture of paints and pigments.

<sup>5</sup> Quantities not comparable because of lack of uniformity in strength of solutions.

<sup>6</sup> The statistics for products reported under other groups cover total production, inclusive of that made with the aid of electricity, and here included to the extent of \$5,042,281 in 1914, and \$2,539,478 in 1909.

<sup>7</sup> Includes number and output of one establishment engaged in the preparation of alumina.

<sup>8</sup> In addition, there were made in electric furnaces in 1914 by 14 establishments in the iron and steel industry, 21,548 tons of foundry iron and steel ingots and castings, chiefly direct steel castings.

TABLE 108 (Continued)

## VIII.—Chemical Substances Produced by the Aid of Electricity (Continued)

|                                                                                                                                                                                      | 1914         | 1909         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------|
| Oxygen and hydrogen:                                                                                                                                                                 |              |              |
| Number of establishments.                                                                                                                                                            | 5            |              |
| Value.                                                                                                                                                                               | \$68,441     | \$16,040,080 |
| All other, named in order of value—aluminum, calcium carbide, abrasives, electrodes, sodium and sodium peroxide, phosphorus, silicon, chlorine, carbon bisulphide, and muriatic acid | \$21,578,062 |              |

## IX.—Plastics

|                                                                                                   | 1914         | 1909        |
|---------------------------------------------------------------------------------------------------|--------------|-------------|
| Number of establishments.                                                                         | 24           | 24          |
| Value of products.                                                                                | \$13,895,784 | \$7,472,732 |
| Pyrosilin, including goods sold under trade names—celluloid, fiberloid, viscoloid, xylonite, etc. | \$8,876,509  | \$5,682,379 |
| In partially manufactured form—rods, sheets, blocks, etc.                                         | \$3,778,374  | (1)         |
| Finished goods, manufactured in the producing establishments.                                     | \$5,098,135  | (1)         |
| Rubber substitutes, including finished goods                                                      | \$428,605    |             |
| Other plastics, including artificial silk.                                                        | \$4,590,670  | \$1,790,353 |

X.—Compressed or liquefied gases<sup>18</sup>

|                                                          | 1914        | 1909        |

| Unclassified chemicals.                   | \$12,483,523 | \$18,750,329 |

## XIII.—All other products

|                                           | 1914        | 1909        |
|-------------------------------------------|-------------|-------------|
| Chemical by-products and residues.        |             |             |
| Pyrite cinder.                            | \$399,458   | \$325,632   |
| All other.                                | \$4,010,162 | \$5,558,976 |
| By-products, not chemical.                | \$3,702,017 | \$2,209,078 |
| Amount received for custom work.          | \$888,734   |             |
| Includes citric and lactic acids in 1899. |             |             |

<sup>25</sup> Anhydrous ammonia reported under "Compressed or liquefied gases."<sup>26</sup> Figures not available for total production of crude glycerine, 1914, as that made and consumed in the manufacture of a large portion of the refined glycerine was not reported.<sup>27</sup> Produced by chemical plants, 19,206,084 pounds; by rolling mills, 13,158,859 pounds; by wire mills, 60,113,880 pounds.<sup>28</sup> In addition, 11,690,006 pounds of copperas were made and consumed in the same establishments.<sup>29</sup> Domestic production of sulphur, United States Geological Survey, 327,634 tons (2,240 pounds); imports for consumption, 26,135 tons.<sup>30</sup> Comprises: Acetanilid, acetone oil, acid calcium phosphate and calcium salts, aluminum chloride, antimony salts, arsenic (total production, as reported by the Geological Survey, 4,670 tons, valued at \$313,147), bismuth salts, cadmium salts, carbon bisulphide, cerium salts and alloys, chrome salts, crown filler, ether (not ethyl oxide), glyco-phosphates, hexamethylene-tetramine, iodine recombined and salts of iodine, iodoform, ketones, lithia and lithium salts, salts of magnesium and manganese, molybdenum, Paris green, sesquisulphate of phosphorus, strontium salts, sulphur chloride, titanium salts, trioxymethylene and tungsten

and other fillers are held in solid aggregations which may be molded or shaped. The value of the products reported includes the value of finished goods, such as combs, brushes, other toilet articles, collars and cuffs, buttons, talking-machine records etc. manufactured in the establishments making the plastic material, but does not include that of finished plastic goods made from purchased plastic stock.

The group of compressed or liquified gases (Group 10) embraces all gases which are compressed or liquified for sale, with the exception of illuminating gases (acetylene, Pintsch gas, Blau gas).

The group of fine chemicals (Group 11) embraces chemicals sold in the trade as chemically or absolutely pure; those which are more especially made use of in analytical operations and in pharmacy; and chemicals, like the salts of the precious metals, of a high unit value. The limitations of the group are not sharply defined, and as a result the statistics may not represent the total output of the respective products, since in some cases the data for certain products may have been included with those for unclassified goods, and, as reported at different censuses, may not be strictly comparable.

The figures in Table 108 aim to give the total production of each commodity in so far as the same is ascertainable from the returns, irrespective of whether it is a principal or subsidiary product of the establishment reporting, or the industry under which the establishment is classified. For example, the production of acetic acid, acetone, acetate of lime, and formaldehyde reported in this table includes that made in wood distillation establishments, the figures for which are given in Table 122; and the production of glycerin here reported, both crude and refined, includes the glycerine product of soap works as given in Table 120.

#### CLEANSING AND POLISHING PREPARATIONS

The products of the establishments in this industry include washing, ironing, sweeping, and scouring compounds; laundry and floor wax; pumice stone and tripoli; and especially preparations for cleansing and polishing furniture, floors, wall paper, gloves, metal ware, and cars, automobile body polish, paint and varnish removers, rust and stain removers etc. In Table 106 separate statistics are given for those establishments whose products of chief value were cleansing preparations, and for those making polishing preparations as their chief product.

In addition to the products covered by the table, cleaning preparations to the value of \$520,846 and polishing preparations to the value of \$1,121,178 were reported by establishments assigned to other classifications, principally those making mops, dusters etc. and those making soap.

Some cleansing and polishing preparations may have been reported under "all other products" by the large soap manufacturers and by the few slaughtering and meat-packing establishments where the soap departments were not returned as separate establishments. Washing soda (sal soda) is included under "chemicals."

#### COKE, NOT INCLUDING GAS-HOUSE COKE

The principal product of establishments under this classification is coke obtained by the distillation of coal in coke ovens. From the "by-product ovens" a number

of valuable by-products are obtained—tar, ammonium sulphate, and ammonia liquors. Establishments engaged primarily in the manufacture of gas, and making coke as a subsidiary product, are not included. Statistics of the materials and products for this industry are collected annually by the United States Geological Survey, therefore such data were not reported to the census in 1914. The following table gives the totals for that year as compiled by the United States Geological Survey, in comparison with those for the censuses of 1909, 1904, and 1899.

The total production of coke, including gas-house coke sold and that made and consumed in gas manufacture, was 138,000 tons in 1914 as compared with 41,947,000 in 1909 and 27,857,000 in 1904.

TABLE 120

## SOAP

|                                                     | 1914          | 1909          |
|-----------------------------------------------------|---------------|---------------|

\* Figures not available

There are no statistics giving the quantity or value of drugs ground by establishments classed under "patent medicines and compounds," and "druggists' preparations."

## DRUGGISTS' PREPARATIONS, PATENT AND PROPRIETARY MEDICINES AND COMPOUNDS, AND PERFUMERY AND COSMETICS

*Druggists' Preparations.*—This industry includes all materials for use by druggists in compounding medicines to be dispensed upon physicians' prescriptions or orders. These comprise tinctures, fluid extracts, medicinal sirups, and other liquid preparations; pills, tablets, powders etc.; alkaloids and derivatives (cocaine, codein, morphine, quinine, and strychnine); synthetic medicinal preparations, such as acetanilid, acetphenetidin, phenolphthalein, saccharin, methylsalicylate etc.; medicinal metals and their salts (bromides, acetates, citrates, bismuth etc.); and biological products, such as serums, vaccines, toxins etc. Concerns engaged in drug grinding as their principal business are not included in this industry.

*Patent medicines and compounds.*—This industry consists of "patent and proprietary medicines" which are those sold under the protection of a patent, copyright, or trade-mark, or prepared according to a secret formula; and "patent and proprietary compounds" which include all such compounds not intended for medical use, such as fire-extinguisher compounds, household ammonia, insecticides etc.

*Perfumery and cosmetics.*—This industry comprises cologne, toilet waters, face powders, cold cream etc. and perfumes.

## DYE STUFFS AND EXTRACTS

Establishments in this industry make materials for dyeing and tanning purposes. The products include natural dyestuffs made from wood, bark, or berries; dyeing extracts; artificial dyestuffs, including synthetic or coal-tar dyes and the mineral colors or dyes; tanning extracts and liquors, including chrome tanning solutions; and mordants, assistants, and sizes. The statistics for dyestuffs and extracts given in the table cover the products of establishments manufacturing the same for sale and do not include those made by dye and print works or tanneries and consumed by the same in further processes of manufacture.

Detail statistics of the quantity and value of the products for the censuses from 1899 to 1914, are given in Table III.

## EXPLOSIVES

Establishments included in this classification manufacture blasting powder, black gunpowder, nitroglycerin, dynamite, including all explosives containing nitroglycerine, permissible explosives, guncotton, including pyroxylin, and all other cellulose nitrates; smokeless powder; and all other high-powered powders used as propellants. Table 112 gives detail statistics for materials and products, for the census of 1914, in comparison with 1909.

## FERTILIZERS

Establishments included in this classification manufacture principally "complete fertilizers" by which is meant a mixture of superphosphates with both potash

and ammoniates; ammoniated fertilizers; superphosphates from minerals, bones etc.; concentrated phosphates etc. The production, for sale, of sulphuric and other acids, fish scrap, soda products, oil, bone black, glue, grease, and various chemicals is also reported. Large quantities of some of these products are made by fertilizer establishments for their own use.

The quantity and value of the different classes of fertilizers manufactured in 1914 in comparison with those

for the censuses of 1909, are given in Table 113. The statistics include the fertilizer products of establishments engaged primarily in the manufacture of products other than fertilizers, chief of which are slaughtering and meat-packing establishments and cottonseed oil mills.

The value of all products of the industry proper, which includes some that are not fertilizers, was \$153,196,152 in 1914, as compared with \$103,960,213 in 1909. Including the fertilizer by-products of other industries, the total production of fertilizers in 1914 was 8,432,206 net tons, valued at \$153,260,212. During the period 1909-1914 the tonnage of the fertilizer products increased 50.1 per cent. Some of the materials, such as sulphuric acid and superphosphates, are the products of establishments engaged in this industry, and therefore are duplicated in the total value of products.

#### GAS, ILLUMINATING AND HEATING

Establishments under this classification manufacture illuminating and fuel gas, chiefly by destructive distillation of coal, wood, resins, and oil, or other carbonaceous substances. The production of natural gas, of course, is not included. Many manufacturing concerns convert coal, through imperfect combustion, into "producer" gas for use as fuel or in gas engines. This process, however, is not covered by the statistics of the gas industry, nor is the production of blast-furnace gas. The manufacture of Pintsch gas, used principally for lighting railway cars, which carry it in compressed form, is included, likewise Blau gas and acetylene, whether distributed through mains or marketed compressed in cylinders, as well as the operations of municipal gas plants.

The statistics for the industry do not include those for establishments operating retort coke ovens, for which see Table 109. The gas purchased by the gas companies is largely retort coke-oven gas.

| Materials.                                         | 1914          | 1909             |
|----------------------------------------------------|---------------|------------------|
| Total cost                                         | \$25,626,539  | \$22,811,548     |

| Building at end of year                                 | 1,249         | 2,950             |                   |
| Abandoned during the year                               | 3,675         | 201               |                   |

<sup>1</sup> Includes coal and coking products produced by establishments engaged primarily in the manufacture of products other than those covered by the industry designation.

<sup>2</sup> Not including gas-house coke, the statistics for which will be found under the classification "Gas, illuminating and heating."

<sup>3</sup> Mainly ammoniated liquor sold on pound basis of NH<sub>3</sub>.

<sup>4</sup> Reported to part as anhydrous ammonia and in part as ammonium sulphate or reduced equivalents.

<sup>5</sup> Mainly benzol.

cubic feet, valued at \$181,207,482, and in 1909, 166,667,641 thousand cubic feet, valued at \$141,478,557.

The statistics for materials and products for 1914, in comparison with those for 1909, are given in Table 114.

#### GLUE NOT ELSEWHERE SPECIFIED

The principal products of establishments included in this classification are glue, flexible and liquid; gelatin; and glue jelly or paste, derived from hides, bones, fleshings, and fish.

In addition to the products covered by Table 106 glue and gelatin to the value of \$3,088,764 were made in slaughtering and meat-packing establishments, while fertilizer factories reported glue to the value of \$1,131,243. Other establishments, principally those making sand and emery paper and cloth, tallow, soap stock, food preparations, oleo oil and fish oil, reported glue and gelatine to the value of \$1,772,872, making the total manufacture of glue \$19,725,703 in 1914, as compared with \$16,328,579 in 1909.

#### GREASE AND TALLOW, NOT INCLUDING LUBRICATING GREASES

Establishments in this classification render soap grease from fat, bones, meat, scraps, garbage etc., and render tallow from the solid fat of cattle, sheep, and

<sup>1</sup> Includes 179 cottonseed-oil mills, 64 grease and tallow establishments, 45 slaughtering and meat packing, and 166 distributed among some 15 other industries that produce wastes of fertilizing value.

<sup>2</sup> Figures not available.

<sup>3</sup> Includes 17,430 tons reported simply as potash salts.

<sup>4</sup> Includes fertilizers reported as ammoniated fertilizers but containing both superphosphates and potash, viz., in 1914, 1,519,156 tons; 1909, 522,389 tons; 1904, 775,967 tons; and 1899, 142,898 tons.

<sup>5</sup> Not including 155,634 tons in 1914, and 72,402 tons in 1909, of no value at the works.

<sup>6</sup> Includes chemicals—soda products, acids, etc.—to the value of \$400,597.

other animals. Establishments making grease and tallow reported hides, skins, bones, tankage, fertilizers, poultry feed, dried blood, oils, stearine, cracklings, hoofs, horns, glue stock, ground bones etc.

Table 106 gives separate statistics for those establishments making soap stock, for those rendering tallow, and for those reporting other products, respectively, classified according to the product of chief value.

There is considerable overlapping between the three subclassifications, as soap stock to the value of \$598,876 was made by those establishments rendering tallow and other products, while tallow to the value of \$265,491 was reported by those making soap stock, and other products to the value of \$23,858 were made by tallow plants. In addition, soap stock to the value of \$1,209,334 was reported by the fertilizer industry, and to the value of \$3,742,747 by slaughtering and meat-packing establishments, while establishments assigned to other classifica-

tions, principally glue, reported soap stock to the value of \$1,311,839.

Tallow to the value of \$12,371,206 was reported by slaughtering and meat-packing establishments, and to the value of \$744,143 by establishments assigned to other classifications, principally oleo oil. These amounts are in addition to the products shown in the tables.

#### LUBRICATING GREASES

This classification includes establishments engaged primarily in the manufacture of grease lubricating compounds and axle grease for automobiles, carriages, wagons, and railway cars. The industry was known as "axle grease" prior to 1914, and was first reported separately at the census of 1879.

In addition to the products covered by Table 106 petroleum refineries reported the production of lubricating and axle greases to the value of \$2,293,103, in

TABLE 114

#### GAS, ILLUMINATING AND HEATING

| Number of establishments reporting B. t. units—                    |              |                  |
| Less than 500                                                      | 3            |                  |
| 500 to 599                                                         | 163          |                  |
| 600 to 699                                                         | 577          |                  |
| 700 to 899                                                         | 11           | ( <sup>1</sup> ) |
| 900 to 1,300                                                       | 45           |                  |
| Over 1,300                                                         | 11           |                  |
| Number not reporting B. t. units                                   | 474          |                  |
| Miles of mains                                                     | 58,727       | 45,119           |
| Gas stoves and heaters, number connected with mains at end of year | 5,168,924    | 3,603,435        |

<sup>1</sup> Figures not available.

<sup>2</sup> Includes 61 Pintch gas and 4 Blau gas.

<sup>3</sup> Includes 40 without distributing mains; gas sold compressed in cylinders.

<sup>4</sup> Number operated under same company name: 1914, 377; 1909, 372.

<sup>5</sup> Includes amount paid for lamps and appliances, \$4,013,885, not included in Table 223.

<sup>6</sup> In addition the following products of gas manufacture were produced commercially by 6 establishments in 1914 and 4 in 1909, engaged primarily in other lines of manufacture:

| Products, total value                                                   | 1914      | 1909      |
|-------------------------------------------------------------------------|-----------|-----------|
| Gas:                                                                    | \$158,743 | \$261,802 |
| Cubic feet, thousands                                                   | 56,939    | 40,628    |
| Straight coal                                                           | 41,744    | 27,558    |
| Carbureted water                                                        | 10,154    |           |
| Acetylene (compressed)                                                  | 5,041     | 13,070    |
| Value                                                                   | \$131,979 | \$254,037 |
| Coke:                                                                   |           |           |
| Bushels                                                                 | 114,371   | 44,347    |
| Value                                                                   | \$9,356   | \$3,399   |
| Tar:                                                                    |           |           |
| Gallons                                                                 | 35,100    | 38,370    |
| Value                                                                   | \$2,076   | \$1,372   |
| Receipts from rents and sales of lamps and appliances                   | \$15,332  | \$2,994   |
| <sup>1</sup> Includes 47 Pintch gas, 18 acetylene, and 28 gasoline gas. |           |           |
| <sup>2</sup> Chiefly Pintch gas, acetylene, and Blau gas.               |           |           |
| <sup>3</sup> Includes only those of which the company has record        |           |           |

1914, and establishments assigned to other classifications, principally those making fish and miscellaneous oils, reported lubricating grease to the value of \$1,755,586.

#### INK, PRINTING

The mixing of boiled oil or varnish with black or other pigments to be used in printing is the principal business of establishments in this classification, which includes printing, lithographing, and embossing inks, colored inks, and gold and bronze ink. At the censuses of 1849 and 1879 there was no separate presentation of the statistics, the classification "ink" including both printing and writing ink.

In addition to the products covered by Table 106 printing inks to the value of \$177,672 in 1914 and of \$9,839 in 1909 were reported by establishments assigned to other industries, principally "bags, other than paper," "paints," and "stationary goods, not elsewhere specified."

#### INK, WRITING

Establishments under this classification manufacture inks consisting principally of an infusion of galls, copperas, gum arabic, and pigments of various kinds. At the censuses of 1849 and 1879 only the totals for "ink" of all kinds were given. Establishments making writing inks also reported the manufacture of mucilage and paste in 1914 to the value of \$616,926. This is included in the value of products shown in the table.

In addition to the value given in Table 106 writing ink to the value of \$67,508, in 1914, and of \$59,965, in 1909, was reported by establishments assigned to other classifications, principally those making glue, typewriter ribbons, mucilage, and polishing preparations.

#### OIL, COTTONSEED AND CAKE

The establishments under this classification are engaged primarily in the manufacture of oil, cake and meal, hulls, and linters from cotton seed, and in some cases in the refining of oil. Table 115 presents the statistics for cottonseed products for the last four censuses.

TABLE 115  
COTTONSEED PRODUCTS (TONS OF 2,000 POUNDS)

|                                                                     | 1914          | 1909          |
|---------------------------------------------------------------------|---------------|---------------|
| Cottonseed, crushed, tons                                           | 4,790,774     | 3,798,549     |
| Products, total value                                               | \$212,127,024 | \$147,867,894 |
| Primary products manufactured, whether for sale or for further use: |               |               |
| Crude oil, gallons                                                  | 191,163,261   | 157,115,689   |
| Cake and meal, tons                                                 | 2,191,610     | 1,661,734     |
| Hulls, tons                                                         | 1,385,940     | 1,258,612     |
| Linters, pounds                                                     | 330,624,502   | 174,620,099   |

In addition, cottonseed products to the value of \$2,638,390 in 1914 and of \$2,017,305 in 1909 were reported by establishments assigned to other industries. These establishments crushed, in 1914, 56,854 tons of seed and produced 2,169,758 gallons of crude oil, 25,768 tons of cake and meal, 16,969 tons of hulls, and 3,492,011 pounds of linters. In 1909 they crushed 28,752 tons of seed, and produced 1,212,852 gallons of crude oil, 12,811 tons of cake and meal, 8926 tons of hulls, and 1,152,978 pounds of linters.

#### OIL, ESSENTIAL

Establishments under this classification extract or distill the oils of various plants, such as peppermint, spearmint, wormwood, pennyroyal, wintergreen, fleabane,

tansy, and fireweed. Black birch, spruce, cedar, juniper and sassafras oils, peppermint-camphor (menthol) and witch-hazel extract are among the products.

The decrease in the value of products for the decade 1869-1879 may be accounted for on the supposition that in 1869 the production on farms was included in the manufacturers' statistics, and that in 1879 it was given with statistics of agriculture. The depreciated currency of 1869 also increased the nominal value of the products that year by about one-fifth.

The quantity and value of the natural oils, and of witch-hazel extract produced, and the value of all other products of the essential-oil industry for 1914 and 1909 are shown in Table 116.

TABLE 116

| ESSENTIAL OILS           |          | 1914 <sup>1</sup> | 1909 <sup>2</sup> |
|--------------------------|----------|-------------------|-------------------|
| Number of establishments | Products | 107               | 74                |
| Total value              |          | \$2,565,361       | \$1,773,304       |
| Essential oil, value     |          | \$1,289,482       | \$1,111,805       |
| Peppermint—              |          |                   |                   |
| Pounds                   |          | 363,991           | 305,781           |
| Value                    |          | \$601,617         | \$519,079         |
| Spearmint—               |          |                   |                   |
| Pounds                   |          | 94,209            | 33,400            |
| Value                    |          | \$238,074         | \$83,283          |
| Black birch—             |          |                   |                   |
| Pounds                   |          | 41,178            | 67,053            |
| Value                    |          | \$67,691          | \$102,045         |
| Wintergreen—             |          |                   |                   |
| Pounds                   |          | 6,000             | 22,281            |
| Value                    |          | \$24,538          | \$68,983          |
| Wormwood—                |          |                   |                   |
| Pounds                   |          | 4,702             |                   |
| Value                    |          | \$9,040           | \$338,415         |
| Other essential oils     |          | \$348,522         |                   |
| Witch-hazel extracts:    |          |                   |                   |
| Gallons                  |          | 917,690           | 691,823           |
| Value                    |          | \$575,938         | \$419,793         |
| All other products       |          | \$699,941         | \$241,706         |

<sup>1</sup> Includes two establishments in 1914 and six in 1909 which were engaged primarily in other industries

#### OIL, LINSEED

The expressing of oil from flaxseed is the chief business of the establishments in this classification, but oil cake and meal and ground flaxseed were also among the products. Linseed oil is used principally in mixing paints. In addition to the products covered by Table 106 raw linseed oil to the value of \$1,201,839 in 1914 and to the value of \$1,106,181 in 1909 was made for sale in paint and varnish factories, and to the value of \$84,408 in 1914 and of \$63,100 in 1909, by establishments assigned to other industries.

#### OIL, NOT ELSEWHERE SPECIFIED

The compounding and blending of mineral, animal, and vegetable oils for lubricating purposes and the manufacture of castor oil, oleo oil, fish or whale oil, resinol and neat's-foot oil, floor oil, signal oil, coconut oil, wool oil, palm oil, and lard oil etc. constitute the operation carried on by the establishments in this classification.

Table 106 gives separate figures for the establishments whose products of chief value were "fish oil," "oleo oil," and "all other" oils. In addition to the products covered by the table, oil to the value of \$778,337, chiefly "fish oil," was reported by manufacturers of fertilizers, and "fish oil" to the value of \$164,373 by establishments assigned to other classifications, principally those making miscellaneous oils and grease and tallow.

Oleo oil was reported by slaughtering and meat-packing establishments to the value of \$11,925,832 and

by grease and tallow factories to the value of \$471,771. In 1909, slaughtering and meat-packing establishments reported oleo oil to the value of \$16,475,726, and miscellaneous oils to the value of \$6,350,745, while fertilizers reported oils to the value of \$810,938, and establishments assigned to other classifications reported oils to the value of \$2,651,710.

Miscellaneous oils to the value of \$4,009,602 were reported by slaughtering and meat-packing establishments and to the value of \$3,400,175 by establishments assigned to other classifications, principally those making fish oil, paints, chemicals, food preparations, soap stock, and starch.

### PAINT AND VARNISH

**Paints.**—The principal products of establishments in this industry are pigments, and the mixtures of these with linseed oil, turpentine, benzine, wood alcohol etc. which constitute paint in paste or ready for use. Water paints and kalsomine, stains, and putty are also among

the products. The manufacture of white lead or of zinc white is the sole or principal business of some concerns, while some are engaged solely in paint mixing, using the materials made by other establishments. There is thus considerable duplication in the gross value of products for the industry as a whole. Many manufacturing and other concerns mix paints for their own use, the value of which is not reported; but the materials used for such paints are mainly covered by the data for the paint and varnish, linseed oil and turpentine and rosin industries.

**Varnishes.**—The establishments in the varnish industry manufacture principally varnishes consisting of solutions of gums of various kinds, or of resins, in solvents such as alcohol, linseed oil, turpentine, naphtha and benzine. Among the products are the black varnishes called japans, enamels, and fillers made of linseed oil with powdered glass, ground slate, or silica. In some instances in both paint and varnish establishments other products are reported as made for sale, such as linseed

TABLE 117

## PAINT AND VARNISH

|                                                                      | 1914          | 1909             |
|----------------------------------------------------------------------|---------------|------------------|
| Number of establishments                                             | 856           | 863              |
| Paint industry                                                       | 585           | 588              |
| Varnish industry                                                     | 215           | 203              |
| Establishments manufacturing paint or varnish as subsidiary products | 56            | 72               |
| Certain specified materials used:                                    |               |                  |
| Pig lead—                                                            |               |                  |
| Tons (2,000 pounds)                                                  | 150,762       | 150,163          |
| Cost                                                                 | \$11,488,113  | \$12,380,524     |
| Grain alcohol—                                                       |               |                  |
| Gallons                                                              | 1,061,324     | 356,225          |
| Cost                                                                 | \$436,509     | \$226,724        |
| Wood alcohol                                                         |               |                  |
| Gallons                                                              | 987,451       | 1,325,807        |
| Cost                                                                 | \$422,122     | \$693,362        |
| Linseed oil—                                                         |               |                  |

<sup>1</sup> Figures not available.

<sup>2</sup> In addition, in 1914, 106,791 tons of pigments, valued at \$9,978,710, were made by smelters direct from the ore, and 66,766 tons of natural mineral pigments, valued at \$473,076, were marketed; and in 1909, 87,525 tons of pigments, valued at \$7,963,332, were made by smelters direct from the ore, and 61,137 tons of natural mineral pigments, valued at \$613,153, were marketed.

<sup>3</sup> Includes lampblack and other carbon blacks made by paint and varnish establishments. See Table 107 for bone, carbon, and lampblack statistics.

oil, raw and boiled, and bleached shellac, but larger quantities of such products are made for use in the same establishment.

The inquiry at the present census in regard to specific materials used in the manufacture of paints and varnishes was confined to pig lead, alcohol (grain and wood), linseed oil, and gums. The statistics for paint and varnish products and the consumption of the above-named materials are given in Table 117 for 1914 and 1909.

## PETROLEUM, REFINING

All crude petroleum refineries are included under this classification. The principal products are illuminating fuel, and lubricating oils, gasoline, and paraffin wax. Other products are lubricating and other greases, oil asphaltum, coke, black naphtha, tar, and sludge acid and residuums.

The products of the petroleum-refining industry, statistics for which are presented in Table 118, aggregated \$396,361,406 in value in 1914, as compared with \$236,-

<sup>2</sup> Figures not available. <sup>3</sup> Included under "All other materials."

<sup>4</sup> Quantities represented, sulphur 2,035 tons, pyrites 23,669 tons.

<sup>5</sup> Includes "wet" natural gas estimated at 1,500,208 thousand cubic feet, cost \$92,476, used by refineries.

<sup>6</sup> The production of casing-head gasoline—that made at the wells from natural gas—was 853,053 barrels (42,652,632 gallons). Excluding duplication on account of casing-head gasoline reported by refineries the total production of gasoline was 24,711,565 barrels (50 gallons).

<sup>7</sup> Includes 2,564,812 barrels reported as reduced oil.

<sup>8</sup> Includes partly finished stock, paraffin acid oil, tree sprays, etc.

997,659 in 1909, the increase during the last decade (1904-1914) being 126.5 per cent. This conforms closely to the increase in the cost of crude petroleum used, which was 132.3 per cent. The crude petroleum used increased in quantity from 66,982,862 barrels of 42 gallons in 1904 to 191,262,724 barrels in 1914, or 185.5 per cent, and the refined-oil products aggregated 40,290,985 barrels of 50 gallons in 1899, 46,454,062 barrels in 1904, 89,082,810 barrels in 1909, and 152,944,877 barrels in 1914, an increase for the last decade of 229.2 per cent.

### SALT

All establishments producing salt, whether by mining or by evaporation, as well as those refining salt, are included in this classification. The products include brine, bromine, and calcium chloride. The major part of the business is of the nature of manufacturing rather than of mining or extracting material from the earth.

Statistics of the materials and products for this industry are collected annually by the United States Geological Survey, therefore such data were not reported to the census in 1914. Table 119 gives the totals for that year as compiled by the United States Geological Survey in comparison with those for the census of 1909.

| Product                               | SALT | 1914         | 1909         |
|---------------------------------------|------|--------------|--------------|
| Total value.....                      |      | \$14,070,333 | \$11,327,834 |
| Salt:                                 |      |              |              |
| Barrels.....                          |      | 134,804,683  | 29,933,060   |
| Value.....                            |      | \$10,271,358 | \$8,311,729  |
| Bromine:                              |      |              |              |
| Pounds.....                           |      | 576,991      | 569,725      |
| Value.....                            |      | \$203,094    | \$57,600     |
| Calcium chloride: <sup>1</sup>        |      |              |              |
| Tons (2,000 pounds).....              |      | 19,403       | 12,853       |
| Value.....                            |      | \$121,766    | \$63,198     |
| All other products, value.....        |      | \$3,474,115  | \$2,895,307  |
| Salt, classified by grade (barrels):  |      |              |              |
| Table and dairy.....                  |      | 4,121,574    | 3,042,824    |
| Common fine.....                      |      | 6,237,860    | 7,745,204    |
| Common coarse.....                    |      | 3,789,163    | 2,843,393    |
| Packers.....                          |      |              | 385,802      |
| Coarse solar.....                     |      | 1,080,199    | 1,109,396    |
| Rock salt, mined.....                 |      | 7,577,172    | 5,938,721    |
| Milling, other grades, and brine..... |      | 11,998,715   | 8,667,720    |

<sup>1</sup> Includes solar salt of Porto Rico.

<sup>2</sup> From natural brine; not including that obtained in connection with the manufacture of soda.

### SOAP

Establishments under this classification manufacture chiefly hard soaps, including powdered soaps, toilet, shaving and special soaps; soft soaps, and glycerine.

The statistics for the soap industry, given in Table 120 for 1914 and 1909 include those for the soap factories operated by the owners of slaughtering and meat-packing establishments, as well as for establishments engaged primarily in the manufacture of soap. In 1899 the manufacture of soap and of candles was reported as one industry, the value of products being \$53,231,017. In 1904 the value of the combined products of these industries was \$72,164,062, in 1909, \$114,488,298, and in 1914, \$129,673,164.

The cost of the materials used in the soap industry was \$88,866,786 in 1914, \$72,179,418 in 1909, and \$43,625,608 in 1904, the increase for the ten-year period being 103.7 per cent. The value of all products was \$127,942,441 in 1914, \$111,357,777 in 1909, and \$68,274,700 in 1904, the increase for the ten-year period being 87.4 per cent. With the addition of the by-products from establishments in other industries the total value of soap products was \$135,304,499 in 1914. The chief soap product was hard soap, which, including that made in establishments engaged primarily in the manu-

facture of products other than soap, aggregated 1,032,114 net tons in 1914. Glycerine is an important product of the soap industry. Reference should be made to Table 108 for the total glycerin product, including that of chemical establishments.

### TURPENTINE AND ROSIN

The establishments included in this classification distill the gum exuded from the southern pine, the distillate being turpentine and residuum rosin. Establishments engaged in the destructive distillation of wood are not included here, but under "wood distillation." The industry includes the extraction of the raw material from the trees as well as its distillation. The decrease shown in value of products during the decade 1859-1869 was due primarily to the Civil War.

Table 121 gives the quantity and value of the turpentine and rosin produced in 1914 and 1909.

| Product                              | TURPENTINE AND ROSIN |              |
|--------------------------------------|----------------------|--------------|
|                                      | 1914                 | 1909         |
| Total value.....                     | \$20,990,191         | \$25,295,017 |
| Turpentine:                          |                      |              |
| Gallons.....                         | 26,980,981           | 28,988,954   |
| Value.....                           | \$10,509,527         | \$12,654,228 |
| Rosin:                               |                      |              |
| Barrels (280 pounds).....            | 2,885,077            | 3,263,857    |
| Value.....                           | \$10,329,410         | \$12,576,721 |
| Dross and other products, value..... | \$151,254            | \$64,068     |

<sup>1</sup> In addition, in 1914, 92,401 gallons of turpentine, valued at \$36,617, and 8,027 barrels of rosin, valued at \$44,734, were reported by establishments assumed to be lumber and timber products, and 575,557 gallons of turpentine, valued at \$194,183, and 51,825 barrels of rosin, valued at \$198,165, by wood distillation. In 1909, 18,310 gallons of turpentine, valued at \$7,482, were reported by lumber manufacturers, and 706,868 gallons, valued at \$249,526, by wood distillation. In 1904, 442,185 gallons of turpentine, valued at \$176,521, were reported by wood distillation.

The total production of turpentine in all industries was 27,648,939 gallons valued at \$10,740,327 in 1914, as compared with 29,714,132 gallons, valued at \$12,911,236 in 1909.

The acreage of timber land worked in 1914 was 8,428,088, compared with 8,076,915 in 1909, making an increase of 4.6 per cent. The returns show a very great increase in the use of the cup system of gathering crude gum. In 1914 the number of crops (of 10,500 cups) worked was 11,813, as compared with only 2,383 in 1909, the percentage of increase being 395.7. On the other hand, the number of crops worked by the boxing system decreased from 17,775 in 1909 to 6,353 in 1914, or 64.3 per cent. The number of crops in back-boxed timber increased from 6,795 in 1909 to 8,314 in 1914, or by 22.4 per cent.

### WOOD DISTILLATION, NOT INCLUDING TURPENTINE AND ROSIN

This classification includes establishments engaged in the manufacture of wood alcohol (methyl alcohol), pyroigneous acid, acetates, tar, turpentine, and charcoal by the destructive distillation of wood in retorts, ovens, or kilns, but does not include establishments making spirits of turpentine from the crude turpentine or gum exuded by the southern pine. The statistics include establishments engaged in the refining of crude wood alcohol. In the North the hard woods are generally used with a production of wood alcohol, while in the South wood distillation is usually confined to pine with a production of turpentine.

The statistics for materials, products, and equipment, for 1914, in comparison with those for the census of 1909, are given in Table 122.

Nec Timeo

Nec Sperno

THE rumor mill is always interesting and sometimes it is instructive. The latest, in regard to dyes, comes from a man who knows somebody in Switzerland who knows somebody in Sweden who knows somebody in Holland, and is as follows: After the war the Germans do not anticipate a great export of German dyestuffs and their best colors are not to be exported. Those already known are to be sold in competition against the products of other countries as opportunity offers, but the mysterious new ones, those with unheard of tintorial power and endurance and brilliancy, are to be under embargo for the benefit of German textile manufacturers. They are alleged to have such amazing lustre and bloom and glow and to be so fast against the sun and wash and bleach and wear and mud and all the vicissitudes of tintorial life that the dyes in present use will be wretched stains in comparison. We are not informed whether those with the photo-chemical properties dreamed of by Professor Ciamician, which shimmer with untold radiance as the fabrics colored with them are brought to the light, are included. He imagined a beautiful woman enrobed in such stuffs entering a brilliantly lighted room and growing more resplendent as she approaches. We might as well add this invention to the rumor to give it body and increase its stimulus.

Time has taught us that the composite German under his Prussian constitution does not play a gentleman's game in world affairs, and that if he is carefully observed and all cheating privileges are denied him, his boasting is vain and in point of ability he is no better than the other players.

In making dyes and intermediates he did get ahead of us, and his commercial methods were those of the card sharper's green table to which he so persistently invites his enemies to meet him and which his enemies so persistently decline to do. According to the rumor of the long journey, his present attitude in insisting upon the return of his colonies is to assure himself of a supply of cotton and wool (*sic*) so as to beat the world in textiles. Flax may be obtained from Russia and worked up in conquered Belgium and within the Vaterland, being provided for by the treaty made over the green table at Brest-Litovsk. For the past four years the things he has held sacred have been few in number. Lately he has added this treaty to his collection of sacred things and yet, somehow, it does not convince us of his spiritual growth.

He is a great hunter for vulnerable spots and vulnerable persons and as soon as he finds a foreigner who looks crooked or weak or mentally crippled with vanity, he approaches him with proffers of friendship and profit.

As he finds American men indisposed to accept his advances it will be no more than natural for him to appeal to American women, especially those of fashion and wealth, to buy his wares. And no matter how unwarranted the rumor as we have related it may be, we may be sure that in some way or other, he will make an ardent appeal to American women with proffers of finery after the war. The love of dress is strong among them and neither voting privileges nor political preferences are likely to overcome it. The dye industry is, in great measure, built upon it.

While the composite German is not a person of good taste, like the composite Frenchman, he is remarkable in imitation and in development of the ideas of others. Until he grows rich he is exceedingly industrious. When he has to root deep or die, he roots deep. And we may well conclude that in research in relation to dyes and textiles, he will continue to preserve. We have excellent research laboratories in connection with our leading dye-manufacturing establishments. We believe that in their facilities they are equal to those of the leading German works in time of peace and, as likely as not, somewhat better. In imagination and in chemical understanding we believe the great American laboratories to be as well if not better manned. On the other hand, we doubt if they have the many university connections that some German concerns enjoyed and used, and the American laboratories have devoted most of their time to the herculean tasks of the development of unfamiliar processes and to the achievements of quality and yield. The chances are that just now, the Germans are ahead of us in novelties. It is well to bear this in mind anyway, and to remember that as soon as we grow scornful and think they are not to be feared any more, they will rise again. At the dye symposium at the Cleveland meeting of the American Chemical Society, the chairman, Mr. R. Norris Shreve, pointed out that the American color industry cannot endure without constant and intense research—in fact, he declared that without it we are bound to fail. We cannot give too much emphasis to this wise statement, which is the very point we have been trying to illustrate.

Another report that comes by less roundabout way is that in the amalgamation of the German dye industries, the Verwaltungsrat or controlling body is made up of technically trained men. The selling staff tells what can be sold and is to report on markets while the financial advisors determine gross expenditures, but control will rest with men who do not require a treatise on chemistry to make them understand proposed measures. If they have their entire dye industry in such hands they are ahead of us in this respect. We do not want to harp on this subject too often but we are firmly convinced that the weak spot in far too many American industrial concerns is in the board of directors. A man does not think that he is entitled to sit on the board of directors of a bank because he deposits his money there, and no more should he presume to inflict his ignorance upon a manufacturing establishment because he has some money invested in it. Shareholders should be represented on boards by the co-operation and wisdom and understanding of the whole body and not by the ignorant and incompetent guardians of special interests. Such men cannot possibly understand technical problems as they arise, and they cannot judge

properly when to say yes and when to say no. It is high time to go through some boards of directors of chemical organizations with a fine-tooth comb to remove the dandruff.

## Sulphuric Acid

### A Martial Indicator

High-school chemistry text-books of twenty-five and thirty years ago contained a statement regarding sulphuric acid that always held the attention of the student even though it was beyond his comprehension. This was to the effect that the consumption of sulphuric acid is an index of the degree of civilization of a people. The reader probably will recall earlier or later statements to the same effect, having reference, of course, to the peaceful pursuits and industries of a nation. But what of sulphuric acid in war? Of what is its consumption then an index? Perhaps a terse answer would be: Of the intensity and magnitude of the military operations.

In 1917 our production was over 7,000,000 tons, nearly twice that of 1913 which may be taken as a normal pre-war year. Plainly the consumption of sulphuric acid is an index of something more than the civilization of a people.

Additional information of unusual interest is contained in the report of the U. S. Geological Survey on the production of sulphuric acid in 1917. Compared with 1913, the last normal year prior to the war, the production for 1917 was nearly twice as great, the increase occurring in the acids of strengths higher than 66 degrees Baumé. The significance of this is, of course, that acid of high strength enters into the manufacture of munitions of war, and with the nations of the world straining every resource at their command for the production of munitions at a high rate of speed and in hitherto unheard-of quantities, sulphuric acid production increased out of all proportion to peace-time outputs.

The dislocation of world trade and commerce by the war had its effect on sulphuric acid production, and for a time the uncertainty of a ready supply of sulphur was disquieting. Wholly unmindful of the machinations of the Potsdam gang, our sulphuric acid industry had been built up largely on the use of pyrites imported from Spain. Thus in 1912 we imported 970,785 long tons of pyrites containing more than 25 per cent of sulphur; in 1913, 850,592 tons; in 1914, 1,026,617. This high mark was followed by a slump in 1915 to 964,634 tons; and this, in turn, by a rise to 1,244,662 tons. In 1917 the imports fell off to the level of 1912 and 1915, amounting to only 967,340 tons.

With these disturbances it became necessary to re-adjust our industry to the use of domestic sulphur-bearing materials and in some cases to remodel plants to burn native sulphur in place of pyrites. There was a wide search for sulphur-bearing ores throughout the United States, and while it can be said that we have ample supplies of sulphur-bearing ores, this does not easily solve the problem of acid production. There has been reluctance to use certain ores, notably pyrrhotite, on account of the changes in practice which would be involved. Regardless of these difficulties, however, and the further problems of labor shortage and transportation, the industry is serving the warring nations with remarkable ability.

## Sidelights on the Exposition

IT IS not only little children that want to see the wheels go round. The crowd likes to see things moving, provided something is happening in the process that those who compose the crowd can understand. A series of mystical prayer wheels, whirling about as is shown in the last act of *The Magic Flute* will cause anybody to stop and look as he passes by, but there needs to be some sort of an answer to the prayer going on to attract his sustained attention. A number of exhibitors have availed themselves of this disposition of persons to close in and see what is happening, and with considerable success. Thus visitors hover about a Dorr thickener and a Benith rotary filter in operation. They watch a pretty glass-and-brass model of a Ruggles-Coles direct-heat dryer turning about with material passing through it. They gather around a furnace burning powdered coal designed to heat apartment houses and office buildings shown by the Powdered Coal Engineering and Equipment Co. and about the dyeing operations in process in the booth of the National Aniline & Chemical Co. We mention these merely as examples, for there are many others.

\* \* \*

The Solvay Process Co. has a thrilling panorama of a war scene. There are aeroplanes in the air, a burning village in the distance, artillery at work, tanks big and little going out, wounded men on stretchers before a dressing station, ambulances going and coming, a Y. M. C. A. hut—in short, nearly everything except the smell of battle, the noise, the misery and the hate. Then hung up above and at the sides of the picture are Solvay products and the uses to which they are put in war, all clearly indicated. The Somet-Solvay Co. also shows a connected display of coal and its products while their relations to each other are indicated by silk ribbons which bind them together.

\* \* \*

It was a happy idea to mark exhibits of things made in the U. S. for the first time since the war began with a bull's eye. We shall make note of some of these occasionally as we proceed, but we give notice here and now that these comments are in no sense a catalogue of the show. They are merely side lights and we deny all obligation to observe a proper sense of proportion.

\* \* \*

The Barrett Company displays a long list of products marked with the eye that sees red. These include anthracene, carbazol, orthocresol, meta-paracresol, various forms of paracumaron resins, resorcline, pyridine and others. The same company shows a remarkably interesting coal-tar tree of unusual detail, in which not only the names of a large number of coal-tar derivatives are given but also a sample bottle of each product, displayed in its proper place.

\* \* \*

The Anaconda Copper Mining Co. has, of course, a considerable display of copper and we also find, side by side, samples of tellurium and selenium. About an equal amount of each of these cousins to sulphur is shown, but we doubt if any copper refiner maintains the same sentiments towards both of them. We understand that there is almost a greater demand for

selenium than the market can meet whereas tellurium is still looking for a job. Here's a good chance for a doctor's degree and a fortune for some aspiring young research chemist, in the discovery of an industrial use for tellurium. The principal application of selenium is said to be in correcting the color in glass, owing to its red effect. At all events that is one large use. We heard a rumor that some of it goes into the dyestuff industry, but we are addicted to doubt in this direction. On the other hand, we throw out a suggestion free of charge to the prospective research wallah in tellurium: Why not make tellurium dyes in the place of sulphur colors? Tellurium is cheap and it has a grand heft. Moreover, next to body and bloom in color, textile people are often made glad by the excess weight that accrues to fabrics in the dye bath.

It does not take much of a strain upon the memory to recall the time when certain wise men refused to consider electrolytic zinc with that quality of faith which is the substance of things hoped for. But here it is, in handsome quantities, 99.9 per cent pure.

\* \* \*

Major F. E. Breithut, who has Uncle Sam's exhibit in charge is connected with the personnel division of the Chemical Warfare Service. He tells us that the immediate, return-mail responses to the questionnaire lately sent to chemists over his name, have numbered over 7000.

\* \* \*

The face-piece of the captured German gas-mask shown in the exhibit of the Chemical Warfare Service is made of softened leather instead of rubber, for obvious reasons. The edges are of cotton fabric, covered with some sort of varnish. The tubes are made of similar cloth and inclose coiled springs of metal, to give them the necessary elastic effect. It is a clever make-shift.

\* \* \*

Corporal Charles F. Roth of the Chemical Warfare Service is, in private life, joint manager of the Exposition with Mr. F. W. Payne, and Secretary of the New York Section of the American Chemical Society. It isn't letting the cat out of the bag to say that when, under the selective draft, Mr. Roth was called to the colors, it became necessary for his associate, Mr. Payne, to cinch up his belt and, metaphorically speaking, spit on his hands for the job ahead of him. A year ago, in the comedy of circumstances, the manager of the Exposition would, as likely as not, have been set to work to peel potatoes in some camp while the authorities were in despair to know the very things in which this cheerful corporal is peculiarly well posted: as to who makes what. A month or so ago, however, when we saw him for nearly the first time in uniform since he wore a little sailor suit as an angel child, he had just been transferred to the Chemical Warfare Service, and he was working like a beaver to speed up production. A modest, gentle-spoken soul is the corporal, far rather disposed to sweet reasonableness than to the sway of might. He is not of the shouting kind. His name has a German turn to it, but that comes from earlier generations, and we can no more imagine him making Prussian noises than we can imagine him mutilating children.

## The Direct Determination of Sulphur Dioxide in Burner Gases

BY F. N. WILLIAMS

WITH the urgent need of higher efficiency and conservation in the use of sulphur, proper burner regulation and furnace control are matters of the utmost importance.

In order to obtain the maximum yield of sulphur dioxide, either from the direct combustion of sulphur or pyrites, regular analysis of the burner gases is most imperative. In this way only can the proper air regulation and burner temperature be obtained. There are two general methods for the determination of sulphur dioxide. The first is by means of an apparatus of the Reinsch type, in which a measured volume of the gas is passed through suitable absorption bottles containing standard iodine solution. The end point is determined either by the disappearance of the color of the iodine or by the titration of the excess of iodine with sodium thiosulphite. In the writer's experience this method is open to several very serious objections, as follows: It is slow and tedious, completeness of absorption is always uncertain, as there is no way of checking back the sample to see if all of the sulphur dioxide has been absorbed. The apparent volume of the gas measured is also uncertain, due to difficulty in maintaining constant temperature and pressure conditions. Further, even the calculation of the percentage of sulphur dioxide is based upon the use of empirical factors which may or may not apply to the conditions of the analysis. The direct method for the determination of sulphur dioxide, as well as all other chemical gases, such as chlorine, hydrochloric acid gas, oxygen, carbon monoxide and others is not open to the above objection, but on the other hand, is rapid, accurate and reliable.

With the instrument illustrated in Fig. 1, an accurate determination of the percentage of any of the above gases may be made easily in less than five minutes, including the time required for taking the sample.

This is a modification of the Orsat, combining the many good qualities of this instrument with the elimination of its faults. Its manipulation is simple and easily mastered, even by those not experienced in chemical laboratory work. It is portable and self-contained, easily carried to any part of the plant.

To make an analysis, it is only necessary to set or hang up the instrument near the source of supply of gas to be tested and connect sample tube, after which a measured volume of 100 cc. of sample is taken into the instrument when, by raising the leveling bottle, the sample is passed through the absorbing solution in the special bubbling pipette, after which the unabsorbed residue is returned to the burette and measured. The percentage of gas absorbed is read off directly on the graduated measuring burette. The operation may be repeated and if the reading is found to be constant, completeness of absorption is certain.

In the proper regulation of sulphur burners, a determination of the amount of air or oxygen in the

combustion gases is most important. The same instrument is used for the determination of oxygen in the damper regulation, as well as for the detection of air leaks in the line.

In addition to the many advantages of simplicity, accuracy and rapidity, the Williams improved gas apparatus has the widest possible range of adaptability. The same instrument may be used for flue-gas analysis in the boiler room, the determination of sulphur dioxide, chlorine, hydrochloric acid and other corrosive

FIG. 1.—WILLIAMS GAS ANALYSIS APPARATUS

gases, as well as for the complete analysis of combustible, illuminating and fuel gases.

### Gas Analysis With Very Small Quantities

An apparatus is described by means of which very small quantities of gaseous mixtures may be analyzed, and in which, during the analysis, the gas comes in contact only with glass, platinum, and mercury. The gas is freed from moisture and carbon dioxide by cooling with a mixture of solid carbon dioxide and alcohol and with liquid air respectively, then burnt by means of a platinum spiral, after addition of oxygen or of hydrogen if necessary; excess of unburnt oxygen is determined by adding hydrogen and again burning, the use of an iron spiral having proved unsatisfactory. A capillary tube is used for the combustion, and if this be effected at a low pressure combination of nitrogen and oxygen and of oxygen and mercury vapor may occur and lead to incorrect results. The use of automatic pumps of the Sprengel type for transferring the gas from one part of the apparatus to another is also inadmissible, as gas occluded by the mercury is liberated when the pressure falls very low and may pass into the measuring tube. The use of Töpler pumps overcomes this difficulty. Results obtained with quantities of gas of the order of 10 cu.mm. are given. In the case of a mixture of  $H_2$ , 26.7, CO 22.7,  $CH_4$ , 22.9, and  $N_2$ , 27 per cent, the values found were  $H_2$ , 26.4, CO 21.1,  $CH_4$ , 24.2, and  $N_2$ , 28.3 per cent.—*Z. anal. Chem.*

## Program of Fourth National Exposition of Chemical Industries

Grand Central Palace, New York  
Week of Sept. 23, 1918

The addresses comprise a series of symposiums devoted to a consideration of

THE DEVELOPMENT OF CHEMICAL INDUSTRIES IN THE  
UNITED STATES, NOTABLY SINCE JULY, 1914.

Wednesday, September 25th.

Afternoon (2:30 P.M.) Symposium: POTASH.

C. A. HIGGINS (Hercules Powder Co.), Recovery of Potash from Kelp.

LINN BRADLEY (Research Corporation), Recovery of Potash from Iron Blast Furnaces and Cement Kilns by Electrical Precipitation.

JOHN W. HORNSEY, Potash from Desert Lakes and Alunite.

ALFRED DE ROPP, JR. (American Trona Co.), Potash from Searles Lake.

Evening (8 P.M.) Motion Pictures.

Electrical Precipitation of Potash from Cement Dust (Research Corporation).

\*Colloid Chemistry.

The Operation of a By-Products Coke Plant (2 reels). (H. Koppers Co.)

Moving a Forest to France (4 reels). (Southern Pine Association.)

The Story of Potash—Production at Searles Lake.

Thursday, September 26th.

Afternoon (2:30 P.M.) Meeting: AMERICAN CERAMIC SOCIETY—Chairman, L. E. Barringer.

L. E. BARRINGER—Manufacture of Electrical Porcelain (Illustrated, Motion Picture).

A. V. BLEININGER—Recent Developments in the Ceramic Industries.

H. RIES—American Clays.

F. A. WHITAKER—Manufacture of Stoneware (Illustrated, Slides).

J. B. SHAW—Fuel Conservation.

S. C. LINBARGER—Carborundum Refractories.

These will be followed by motion pictures as designated for the evening program.

Evening (8 P.M.) Motion Pictures.

THE CERAMIC INDUSTRIES

Glass Making (Corning Glass Co.)

†The Making of Cut Glass.

Manufacture of Electrical Porcelain (General Electric Co.).

†The Making of Pottery.

(9 P.M.) Speakers:

J. A. SWITZER (University of Tennessee), Waterpower Potentialities of East Tennessee.

HERBERT C. HENEGAR (American Zinc Co.), Mineral Resources of East Tennessee.

## From A to Z with the Exhibitors

IN THIS and succeeding daily issues of CHEMICAL & METALLURGICAL ENGINEERING published during the Chemical Exposition will be found brief descriptions of more than 300 exhibits. In order that the record might show the progress that has been made since we entered the war, we have asked the exhibitors to inform us which of their products have been made in this country for the first time since the war began. At the exposition itself the visitor will notice many chemical products marked with a bull's-eye as the distinguishing mark of such progress.

PAUL O. ABBE: Single specimen, assay and jar mills, direct-connected to motors. Duodecuple assay mill, improved rotary cutter, hammer mill, and pony mixer. In charge of exhibit: Mr. ABBE, Miss LAMA.

ABBE ENGINEERING CO.: Patented pulverizing and grinding machinery; laboratory grinding mills; rotary cutters. Special laboratory mills for pulverizing chemicals have been developed since we entered the war. In charge of exhibit: H. F. KLEINFELDT, H. C. RUSS, W. S. RANSOM.

AMERICAN BLAUGAS CORPORATION: Blaugas for operation of laboratory gas appliances and for industrial heating purposes. Dri-Gas for welding, cutting, and brazing. The latter is a new product since the United States entered the war. In charge of exhibit: G. E. BEVES, T. F. HINTZE.

AMERICAN CERAMIC SOCIETY: Charts showing in simplest possible form the size and importance of the ceramic industries both in themselves and in relation to other well known industries.

AMERICAN CHEMICAL & MFG. Co.: Chemical oils, lacquer, technical coatings, acid-proofing and water-proofing, protective coatings for airplanes, submarines, auto-cars, steel cars, steel construction, etc. The new developments since we entered the war are coatings for concrete ship bottoms; anti-fouling ship-bottom paint; pyroxilin coatings for airplanes. In charge of exhibit: W. M. VAN OSTROM, CHAS. D. STILLMAN, F. E. SINCERE, R. C. DEDERICK, E. K. CHAFFEY, F. K. LOCKHART.

AMERICAN CYANAMID CO.: A complete set of cyanamid products: cyanamid, aqua ammonia, nitric acid, ammonium nitrate, sulphate of ammonia, ammo-phos, urea, dicyandiamid, cyanide and Florida pebble phosphate. Cyanamid is the only one of these products produced prior to the war; all others have been developed since 1914. A series of samples will show the steps in the manufacture of cyanamid. Urea is a product that has come into considerable prominence on account of its use as an acid absorbent in nitrocellulose and lacquer used on the fabric of aeroplane wings. Its presence in the dope neutralizes the slight traces of nitric acid that slowly develop and which would otherwise attack and weaken the fabric. Photographs and charts will complete the exhibit. In charge of exhibit: E. J. PRANKE.

AMERICAN ELECTROCHEMICAL SOCIETY. Heavy Browning machine gun in the manufacture of which artificial abrasives are used for between sixty and seventy grinding operations, chrome-carbon alloy steel, manufactured in the electric furnace, is used for the barrel; 8-in. army shell and 6-in. shell, trench hat.

list of processes used extensively in modern warfare; collection of products of electrolytic cell and of the electric furnace, together with photographs of waterpower devices. In charge of exhibit: CARL G. SCHLUEDEBERG.

AMERICAN ANILINE PRODUCTS, INC. A practical exhibit of dyestuffs.

AMERICAN KRON SCALE Co.: Kron automatic dial scale, 1000 lb. capacity, with platform 46 x 36 in., equipped with tare beam for automatic deduction of tare weight. In charge of exhibit: E. OHNELL.

AMERICAN-LA FRANCE FIRE ENGINE Co., INC.: Respirators for protection against dust and fumes. Filter masks for various dust and poisonous fumes. The latter article is a new development following somewhat the idea of the army trench mask.

THE AMERICAN METAL COMPANY, LTD. The following products will be exhibited: Arsenic oxide, coal, copper, copper sulphate, ferroalloys, gold, lead and antimonial lead, molybdenite, muriatic acid, pyrites, salt cake, silver, spelter, sulphuric acid, tin, tungsten concentrates, zinc dust, oxide and sulphate. A special feature is the production of molybdenum concentrates on a large scale. In charge of exhibit: H. M. BURKEY.

AMERICAN METER Co.: Apparatus appertaining to the correct measurement and testing of gas, including calorimeters, siphon gages, sulphur tests, wet test meters, diaphragm dry meters, iron case meters, Tobey meters. The central feature of the exhibit is the calorimeter. In charge of exhibit: ERNEST KERSTEIN.

AMERICAN PIPE BENDING MACHINE Co.: "Wonder" pipe bending machines in two models. In charge of exhibit: E. T. BLAKE, GEO. W. GRAHAM.

AMERICAN WATER SOFTENER Co.: "Delcalso" zeolitic water softener. Glass apparatus will be in operation in which interested persons can soften any samples of water which they may bring with them. This device has been developed and brought out, since we entered the war. In charge of exhibit: R. W. CONRAD.

ANILINE DYES AND CHEMICALS, INC.: Dyestuffs, intermediates and chemicals which are the products of the company's various factories. Many of the dyes and intermediates have been developed since 1914. In charge of exhibits: W. H. VAN WINCKEL.

APEX CHEMICAL Co., INC.: Chemical products used in the textile, leather and allied industries. Since the United States entered the war this company has produced the following chemicals: antimonelle, a substitute for tartar emetic; orthophene, for freeing lime from hides; lactic and formic acids. In charge of exhibit: Dr. S. M. HERMANN, HUGO HELBURN, CHARLES D. RASENBERGER, NELSON CRAIG.

ARKELL SAFETY BAG Co.: "Arksafe" elastic paper lining for barrels, drums, boxes and bags. These linings prevent the sifting of powdered materials from packages and keep the contents clean and dry. In charge of exhibit: C. J. MORALES.

ARNOLD HOFFMAN & Co., INC.: Joint exhibit with Mathieson Alkali Works, Inc., and Nitrogen Products Company. Exhibit of bleaching powders, liquid chlorine, caustic soda, soda ash, sodium bicarbonate and modified sodas, sodium cyanide, red and yellow prussiate of soda and anhydrous ammonia. Pigment colors, gums, dextrine, oils, softeners and textile finishing materials. In charge of exhibit: A. L. HAYES.

BARIO METAL CORP.: Bario metals used in some cases as a substitute for platinum. Electric resistance furnaces. Both the metal and the furnace have been developed since we entered the war. In charge of exhibit: PAUL DEMILES.

BAYONNE CASTING Co.: Monel-metal castings, nickel castings and hot-rolled monel-metal rod. Fabricated monel-metal shapes. In charge of exhibit: H. F. CHASE.

BAUSCH & LOMB OPTICAL Co. A complete photomicrographic outfit for metallographic work, suitable for work with high magnifications; a complete compound metallurgical microscope and smaller accessories. In charge of exhibition: R. C. DEAN.

BEACH-RUSS Co.: Patented rotary high-vacuum pumps, rotary pressure blowers. Extra high-vacuum pumps for chemical plants have been developed since we entered the war. In charge of exhibit: H. C. RUSS, A. T. BEACH, C. A. BEACH.

CHRISTIAN BECKER, INC.: Becker analytical balances, including chainomatic analytical balance and chainomatic specific gravity balance. Torsion balances. The chainomatic balances are new developments since we entered the war. In charge of exhibits: S. W. HESS, Miss C. L. BECKER, A. T. MILLROY.

BECKLEY PERFORATING Co.: Perforated metal products and miniature reproductions of tanks and special shapes in sheet metal which have been furnished to various chemical industries. Tanks and special shapes are electrically welded. In charge of exhibit: ALLEN L. PRICE.

BETHLEHEM FOUNDRY & MACHINE Co.: Castings made of corrosion. It has been necessary for the present to discontinue the manufacture of tantiron castings owing to shipping difficulties. New developments since the war began have been along the line of confidential work for clients. In charge of exhibit: J. GEORGE LEHMAN, R. E. WILBUR, GEORGE ETTLE.

BOYER OIL Co., INC.: Oils and fats, including castor, cocoanut, corn, cottonseed, cod, linseed, mustard, olive, palm, peanut, rapeseed, sesame, soyabean, walnut and whale oils. In charge of exhibit: Mr. KIENLE.

BRISTOL Co.: Recording and indicating instruments for pressure, temperature and electricity.

BUTTERWORTH-JUDSON CORP.: Dyestuffs, intermediates, heavy acids, salt cake, nitre cake, lithopone.

A. M. BYERS Co.: Genuine wrought iron pipe, showing the method of marking every length with name and year of manufacture. Samples of pipe taken from service in an effort to determine relative life of iron and steel pipe. In charge of exhibit: R. W. KENNEY, N. BOLAND.

JOHN CAMPBELL Co.: Aniline colors and coal tar products. Since the United States entered the war this company has produced a full line of direct, basic chrome, acid and sulphur colors sold under trademarked American names. The line is being constantly enlarged. In charge of exhibit: GEORGE H. WHALEY.

CANADA CARBIDE Co., LTD.: Samples of domestic and export sizes of carbide; domestic and export packages; projection lantern and colored slide. In charge of exhibit: H. E. MUSSETT.

CANADIAN CHEMICAL JOURNAL: A representative will be in charge to give information on Canada, statistics

of Canadian products, especially those relating to the chemical and metallurgical industries. In charge of exhibits: E. B. BIGGAR, L. E. WESTMAN.

**CARBORUNDUM CO.:** Carborundum protection pyrometer tubes, carborundum fire sand, silicon metal. Carborundum resistance rods for use as lightning arresters or similar work where a static resistance only is required. Miscellaneous exhibits of small refractories made from silfrax. High grade fire brick, carbofrax and refrax.

**CARRIER ENGINEERING CORP.:** Model Carrier system of air-conditioning in operation. Samples of materials in the manufacture of which the Carrier system plays an important part. In charge of exhibit: J. I. LYLE, E. P. HECKEL, L. L. LEWIS, M. S. SMITH, GEORGE SCHMIDT.

**CELLULOID ZAPON COMPANY.** Lacquer enamels and varnishes, bronze liquids, amyl acetate, soluble cotton.

**CENTRAL DYESTUFF & CHEMICAL CO.** Coal-tar colors and intermediates. In charge of exhibit: M. UNDERLEIDER, A. F. WIEHL, E. MONTALENT.

**CENTRAL SCIENTIFIC CO.:** Laboratory specialists; de Khotinsky constant temperature apparatus, Parr Calorimeters; balances and weights; electrical instruments. Since the United States entered the war the company has produced special analytical balances, vacuum pumps, stills and rotary blowers. In charge of exhibit: S. L. REDMAN.

**CHEMICAL CO. OF AMERICA, INC.:** Intermediates for dyestuff manufacture, in addition to which will be featured a khaki color. In charge of exhibit: Messrs. KENDALL and CHRIST.

**CHEMICAL CONSTRUCTION CO.:** Blueprints showing the installation of different kinds of acid plants constructed by the company. A model acid-proof masonry tower showing detailed interior construction. Samples of acid-proof brick and acid-proof cement joints. The acid-proof masonry has played an important part in the construction of government nitrate plants throughout the country. The spiral chemical packing rings for use in absorption towers have been produced in excess of 100,000,000 this year. In charge of exhibit: R. L. RUTZLER, T. C. OLIVER.

**CHEMICAL WARFARE SERVICE, NATIONAL ARMY:** Information bureau regarding industrial relations and university relations. Exhibit of gas masks by Gas Defense Division. Exhibit of Gas Offense and Research Divisions. In charge of exhibit: Maj. F. E. BREITHUT.

**CLINCHFIELD PRODUCTS CORPORATION:** Full line of products, including sodium sulphide, barium carbonate, barium chloride, barium sulphate, barium sulphide, Glauber's salts, and ground feldspar. In charge of exhibit: J. G. HARRIS.

**CRANE CO.:** A line of valves, fittings, and specialties for steam-power, heating and process work and for water, gas, and chemical purposes. The feature of the exhibit will be a complete steam plant in actual operation, demonstrating the company's products but particularly the boiler-feeding system. In charge of exhibit: W. L. OSWALD, WM. FINK.

**CRANE PACKING CO.:** "John Crane" babbitt foil metallic packing, which is made of very thin sheets of babbitt foil, spirally wound to allow of the greatest amount of compression and flexibility. This material

is specially applicable to use in the chemical industry. Centrifugal water-pump sets of packing will be shown, and asbestos copper foil wrapped packing for superheated service. In charge of exhibit: F. E. PAYNE, JULIAN N. WALTON.

**CRESCENT COLOR & CHEMICAL WORKS, INC.:** An exhibit of dry and pulp colors. In charge of exhibit: N. A. MCMAUS, JAMES MURRAY, JOHN GLEDHILL, V. J. CHARTRAND.

**CRESCENT INK & COLOR CO., INC.:** An exhibit of the manufacture of ink. In charge of exhibit: N. A. MCMAUS, JOSEPH M. PETRY, WALTER A. CONLAN.

**CROMOS CHEMICAL CO., INC.:** A display of benzoic acid, benzoate of soda and benzyl chloride. In charge of exhibit: I. MARK, J. H. LYONS.

**J. H. DAY CO.:** Mixing machines for handling powders, liquids, and pasty materials. In charge of exhibit: R. W. WALLACE.

**DENVER FIRE CLAY CO.:** Laboratory and plant specialties including furnaces, crushers, samplers, screens, fire-clay products, electroscope equipment for testing radioactivity, oil and gas burners. In charge of exhibit: J. S. KING, E. R. HARRIS.

**DETROIT RANGE BOILER CO.:** "Perfect" metal bilge barrel and drum, used as steel containers in the chemical industry. The tight barrel is suitable for handling liquids. The removable-head barrel can be used for powders, semi-solids, heavy liquids, and other products the emptying of which requires the entire head to be taken out of the barrel. In charge of exhibit: W. B. GOGGARD.

**J. P. DEVINE CO.:** Vacuum drying chambers of several sizes made up in complete installation form, with all necessary fittings, mountings and auxiliaries, a condenser and a rotary valve vacuum pump; a high-pressure cast steel autoclave; copper distilled-water outfits capable of delivering 5 gallons of pure distilled water per hour; a double-effect vacuum evaporator suited for the experimental and research laboratory; some chemical equipment and a display of photographs. In charge of exhibit: J. P. DEVINE, NATHAN OWITZ, L. W. TREICHLER, A. D. RENNER, A. M. FRANTZ, E. H. MILLER.

**DIAMOND STATE FIBRE CO.:** Diamond fibre products including receptacles for mills, fibre sheets, rods, and tubes employed in the electrical industry. Features developed since the war are red spinning parchment, Diamond-F food-protective papers. In charge of exhibit: T. M. BOGERT.

**DORR CO.:** The Dorr agitator, Dorr bowl classifier, Dorr tray thickener, and Dorco pump in closed circuit, demonstrating their various functions in a number of different chemical processes. A pulp containing different materials will be mixed in the agitator, separated in the classifier, thickened and dewatered in the thickener, and handled by means of the pump. This equipment has recently entered into the construction of several explosive plants built for the Government. In charge of exhibit: H. N. SPICER.

**DYE PRODUCTS AND CHEMICAL CO., INC.:** A display of dyestuffs and intermediates used for the manufacture of khaki dyestuffs for U. S. Government uniforms showing the various steps necessary in the manufacture of these materials. In charge of exhibit: SIDNEY SIMON, L. M. LOWENTHAL, CLARENCE K. SIMON.

## Development in Nitric Acid Manufacture in the United States Since 1914\*

Nine-Fold Increase in Production Since War Began—Ammonia Oxidation Process May Be Greatest Source of Production After the War—Data on Catalyzer Efficiency

By E. J. PRANKE

THE production of nitric acid in 1914, according to the census of manufacturers, was 78,589 tons of nitric acid of average strength, and 112,124 tons of mixed acid. According to other data given in the census, these figures represent about 89,000 tons of 100 per cent nitric acid. All of this acid was produced from nitrate of soda, consuming about 160,000 tons of nitrate. The pre-war importation of nitrate of soda amounted to about 560,000 tons per annum; hence the normal consumption for purposes other than the manufacture of nitric acid was about 400,000 tons.

The present rate of importation is about 1,600,000 tons of nitrate per annum. Since very little is going into storage and the total consumption for purposes other than nitric acid manufacture has increased but slightly, if at all, it may be estimated that at least 1,000,000 tons of nitrate per annum is being converted into nitric acid at the present time. This is equivalent to 650,000 tons of 100 per cent nitric acid, of which nearly five-sixths is being used for the manufacture of military explosives.

### IMPROVEMENTS IN RECENTLY BUILT PLANTS

The building of the new nitrates of soda acid plants has offered an excellent opportunity for the introduction of many improvements. The Dutch ovens under the retorts have been displaced by modern fire-boxes provided with a proper arch. This change has effected a saving in coal consumption of approximately 25 per cent. The chemical stoneware from the retorts to the condensers and the glass condenser tubes have been displaced by acid-proof, high-silica iron, such as duri-iron and tantiron. The volvic-ware saucers in the towers have also been displaced by acid-proof iron. The chemical ware from the condensers to the absorption towers, and the glass lines for circulation of acid at the sides and top of the towers, however, are retained. The absorption tower capacity has been increased about 40 per cent by the addition of more towers. Spiral rings for tower packing have taken the place of the ordinary form of packing.

Important changes have also been made in operation. The average charge of 5000 pounds of nitrate per retort has been increased to about 7500 pounds. The retorts, instead of being operated in batches, are now operated in rotation. Instead of three runs per retort per day, the usual practice is now two runs per day. Temperatures are also controlled more carefully than in the past.

The result of these improvements is an increase in the amount of nitrogen recovered as acid from an aver-

age of from about 78 to 80 per cent to about 92 to 94 per cent of the nitrogen in the nitrate of soda. At the same time the labor requirement has been somewhat decreased.

A good beginning has also been made in the recovery of nitroso gases produced in the various nitration operations. In some of the systems that have been devised, as much as one-half of the fumes are being recovered. The collection of the gases from the many nitration units, however, is still a serious problem. While the aggregate amount of acid that is being recovered is large, it represents only a small fraction of the acid gases that are being wasted. In the ordinary nitration operation as carried out at present, about one-tenth or one-twelfth of the nitric acid is wasted in the wash waters, while on an average about one-eighth is lost as fumes, of which one-half is recovered in plants equipped with recovery systems.

Nitric acid by direct combustion of air by the arc process has not had any important development as yet in America. Three small plants, more or less on an experimental scale, have been built in the United States and operated for short periods. The production of these plants thus far has been negligible. The total annual capacity probably does not exceed two or three thousand tons of nitric acid per annum.

Nitric acid by the oxidation of ammonia has received a considerable and important development since the outbreak of the war. In 1914 there were no ammonia oxidation plants in this country. At the present time there are under construction ammonia oxidation plants with a capacity equal to about 225,000 tons of 100 per cent nitric acid per annum.

### DEVELOPMENT OF AMMONIA-OXIDATION PLANTS

The first commercial-sized oxidation plant was established in July, 1916, at the Ammo-Phos Works of the American Cyanamid Company at Warners, New Jersey. Six catalyzer units were installed, each with a presumed capacity of 14 pounds nitric acid per hour. Improvements in the design of the catalyzer and in methods of operation have brought the capacity to over 40 pounds of nitric acid per hour. The catalyzer used is a single fine platinum gauze, with an area of about two square feet, electrically heated. Over a period of two years two of these units have supplied the nitric requirements of the 60,000-ton sulphuric acid chamber plant at this works. The ammonia is taken directly from cyanamide autoclaves producing about 30 tons of ammonia gas per day, used mainly for aqua ammonia manufacture. This plant has served for several months as a training school for the instruction of operatives for the Government cyanamide-nitrates plants. As an

\* A paper read at the Fourth National Exposition of Chemical Industries, New York, Sept. 24, 1918.

example of the normal operation of the catalyzers on ammonia taken directly from the autoclave mains, Table 1 is quoted verbatim from the records for the week July 13 to 19, 1918. Each value is the average of determinations of two chemists working independently, with the exception of those marked (\*) which are determinations of one chemist only.

TABLE 1.—EFFICIENCY OF CATALYZERS IN AMMONIA OXIDATION

#### MUSCLE SHOALS PLANT IN OPERATION NOVEMBER FIRST

The cyanamide-nitrates plant at Muscle Shoals, Alabama, will use the electrically heated single-gauze catalyzer. It will produce approximately 90,000 tons of 100 per cent nitric acid per annum. The plant is expected to go into operation about November 1. The cyanamide-nitrates plant near Cincinnati, and the one near Toledo, Ohio, will also use the same process, each producing at one-half the above rate. They are expected to be in operation early next spring.

The Government experimental plant at Sheffield, Alabama, known as Nitrate Plant No. 1, which will make about 15,000 tons of nitric acid per annum, has adopted a non-electrically heated multiple screen, consisting of several layers of platinum gauze, welded together at points, and rolled into the form of a cylinder. The ammonia-air mixture flows outward through the screen at a rate several times as fast as with the electrically heated single screen. After the oxidation has been started by external application of heat the temperature is self-sustaining from the heat of reaction.

#### NEGLECTIBLE CONSUMPTION OF ELECTRIC ENERGY

In view of the perfect control obtainable with electrical heating, the cost of the electric energy consumed, amounting to about one-third of one per cent of the present market value of the nitric acid, may be regarded as negligible. As to the single versus the multiple screen the efficiencies cited above as examples of normal operation of electrically heated single screens are believed to represent the highest standards yet attained in the practical operation of ammonia catalyzers.

It is understood that the Semet Solvay Company has an ammonia oxidation plant at Syracuse, New York, using the multiple screen without electrical heating. This plant is producing several tons  $\text{NaNO}_3$  per day. Information regarding efficiencies is not available.

In addition to the plants above mentioned, the Navy Department decided about two months ago to build a plant at Indian Head, Maryland, for fixing nitrogen by the modified Haber Process used at Plant No. 1. All the ammonia produced will be oxidized to nitric acid, yielding about 30,000 tons per annum.

Considerable work is also being done on the use of catalyzers to hasten the conversion of the nitrose gases, obtained from the catalyzers, into nitric acid. The object is to reduce the amount of space required for reaction chambers. The experiments along this line show promise of early success.

#### PRODUCTION NEXT SPRING WILL BE NINE TIMES NORMAL

The nitric acid producing rate in the spring of 1919 will be about 650,000 tons from nitrate of soda and about 225,000 tons by oxidation of ammonia obtained from the air, a total of \$75,000 tons of 100 per cent nitric acid. This is about nine times the pre-war normal consumption. In 1914 the industrial explosives industry consumed about 50,000 tons per annum, while all other uses took only about 40,000 tons. The only notable increase in consuming ability since 1914, aside from military explosives, has been in the dye industry. In 1917 it was estimated that 30,000 tons of dyes were produced in America, equal to the total 1914 consumption. The production will probably increase somewhat further, but at most could hardly consume more than 30,000 or 40,000 tons of concentrated nitric acid. With a producing rate of \$75,000 tons, and a consuming ability in peace times of 125,000 tons, or possibly 150,000 tons, it is evident that over four-fifths of the nitric acid producing capacity will have to be shut down as soon as peace conditions are established.

#### AMMONIA-OXIDATION METHOD MAY BE PRINCIPAL SOURCE

The successful development of the ammonia oxidation process raises the question whether this may not become the principal source of nitric acid in the future. While a categorical statement cannot be made, some of the major factors may at least be pointed out. The cost of converting nitrate of soda to concentrated nitric acid is just about equal to the cost of converting autoclave ammonia gas to concentrated nitric acid, interest and depreciation included in both cases. Ammonia gas, however, is a cheaper form of nitrogen than is nitrate of soda. It is cheaper by the amount of sulphuric acid required to fix the ammonia gas in the form of sulphate of ammonia. For nitrate of soda and sulphate of ammonia in the past have always sold at about the same price per pound of nitrogen. They will probably be sold on a competitive basis after the war, or if there is any difference the ammonium form will probably be the cheaper. The differential between ammonia gas and sulphate of ammonia, then, will make a difference of about 15 to 20 per cent in the cost of nitric acid in favor of ammonia oxidation. The fact that the nitrate of soda acid plants are being amortized during the war and are conveniently located for peace-time industrial uses, while new ammonia oxidation plants would have to be built at these same points in order to avoid transporting acid, is relatively not very important, because the interest and depreciation charge saved by amortization of the nitrate of soda acid plants is only about 4 per cent of the normal cost of the acid. The decisive factor will probably be simply the question whether the difference in cost of acid by the two processes is a sufficient incentive to overcome the inertia of human nature against changing existing practices.

## Industrial Developments Relating to the Manufacture of Acetic Acid and Acetone

**Tremendous Demand for Acetone for Explosives Led to Its Production from Molasses, Alcohol and from Calcium Carbide—Wood-Distillation Industry Faces Disaster Unless It Develops Scientifically**

BY HAROLD HIBBERT

Director Research and Technical Division,  
Ralph L. Fuller & Co., Inc.

PRIOR to 1914, more than half the entire world's supply of acetone and acetic acid was furnished through the medium of the wood-distillation industries of this country and Canada, the remainder being contributed principally by Austria-Hungary. When wood is heated in closed iron retorts in absence of air, it undergoes a decomposition whereby certain volatile constituents such as acetic acid, acetone and methyl acetate are driven off, the residue consisting of wood charcoal. In practice the crude acetic acid is neutralized by the addition of lime, which is then converted either into refined acetic acid or into acetone.

Acetic acid is used very extensively in the chemical industry for the manufacture of dyestuffs, pharmaceutical preparations, varnish for aeroplane wings and also as a condiment, while acetone finds its main outlet as a general solvent for varnish, lacquers, and in the manufacture of explosives such as cordite. This latter is used in immense quantities by the British and other Navies, and is made from a mixture of gun cotton with nitroglycerine. In order to "compound" these materials, that is, to enable the gun cotton to become thoroughly incorporated with the nitroglycerine, it is necessary to employ a solvent which in this case happens to be acetone. Many other solvents have been tried out, but this has been found to give the best results. The British Admiralty early foresaw the necessity of obtaining large supplies of this material, and a few months after war broke out they were endeavoring to contract for an immediate supply of approximately 15,000 to 20,000 tons. This amount was considerably more than the entire world's annual production.

According to an article by Messrs. French & Withrow<sup>1</sup>, the annual production of grey acetate of lime in this country in 1914 amounted to approximately 84,000 tons, since increased in 1917 to over 100,000 tons. This is equivalent to about 17,000 tons of acetone if all of it were employed for this purpose. As a matter of

fact the greater part was used for the manufacture of acetic acid, the output of acetone being in the neighborhood of 7500 to 8000 tons annually. Faced with a sudden demand for an immediate increase in this commodity to some 20,000 tons, it was evident that new measures would have to be adopted for its manufacture, since it was altogether impossible to obtain this amount from the wood-distillation industry in the short time available. The assistance of the chemist and chemical engineer were therefore sought, and it is to the credit of the profession that they have provided an eminently satisfactory solution to meet this most urgent demand. The first line of attack was found in an attempt to increase the acetic acid production by the fermentation of various carbohydrate materials, as for example, molasses, through which alcohol and from this acetic acid in turn can be manufactured.

Working in coöperation with the British Government, the U. S. Industrial Chemical Co. has erected a large plant at Curtis Bay, and in spite of the many difficulties encountered both from a chemical, biological and engineering standpoint, they have so far succeeded that they are now manufacturing acetic acid, equivalent to approximately 70,000 pounds of 100 per cent strength per day, which is used for the manufacture of acetone and methyl acetate. This huge amount is all made from vinegar obtained from molasses alcohol by the quick fermentation process.

Some idea of the work involved in such an undertaking may be obtained when it is remarked that it was found necessary to construct special tank steamers for the conveyance of the molasses from Cuba to Baltimore. The generators comprise one series of 200 tanks, 25 ft. by 18 ft., and a second series of 960 of a size of 10 ft. by 18 ft. These are filled with beech shavings through the agency of which the oxidation of the alcohol to acetic acid is effected.

Anyone acquainted with the delicate nature of the changes taking place in such fermentations is well aware of the extraordinary care and oversight which it

is necessary to give to such operations to insure a commercial success, and the fact remains that the plant is now functioning day in and day out with continuous regularity.

To transport the dilute acetic acid liquors to the evaporators requires approximately 35 miles of wooden piping, and the evaporators installed for the concentration of the calcium acetate liquors, which are capable of handling some 200,000 gallons of liquor per day, require for this purpose a power consumption of 3000 horsepower.

While in all probability the manufacture of acetic acid and acetone by this process will not be profitable after the conclusion of peace, there is no doubt but that the company operating this plant will have first claim to be the largest manufacturers of alcohol in the world and the country should be proud of their supremacy in this respect.

#### FERNBACH PROCESS: FERMENTATION OF STARCH

Even with this additional amount of acetone and acetic acid available, it was evident that there would not be sufficient to meet the requirements of the British Government and their Allies, so that other processes came up for discussion. Among these was one relating to the "FERNBACH" process. This consists in the fermentation of starch from corn or other grain by means of a special ferment which has the power of resolving the carbohydrate material into a mixture consisting essentially of butyl alcohol and acetone, the former largely predominating. The conditions of fermentation call for strict, careful chemical and biological control and those responsible for its development are to be congratulated on the successful results obtained. It is understood that the output of acetone at the plant in Toronto now amounts to 100 tons per month, while from the one in this country it approximates close to 250 tons. It would seem that the industrial disposal of the large tonnage of butyl alcohol formed would call for serious consideration, but it should offer no insuperable difficulties to the chemical profession.

Of the other processes calling for consideration, one of the most interesting was that relating to the manufacture of acetic acid from acetylene, regarding which a number of German patents had already been taken out some seven or eight years ago.

It has been known for a considerable period of time that when acetylene gas is passed through a solution of a mercury salt in dilute acid, it combines with the water, yielding a somewhat volatile liquid known as acetaldehyde, from which acetic acid in turn is readily obtained by the action of atmospheric oxygen. While those acquainted with the subject were aware of these developments, and with the fact that a plant had already been in operation in Germany for some two or three years prior to the outbreak of war, it nevertheless came as a great surprise to the majority of those interested that such was in reality the case.

The incident in fact merely furnishes another remarkable instance of the wonderful foresight of the German authorities in providing for their own requirements of such commodities, both from an industrial and especially from a military standpoint. To render themselves independent of this country in the matter of acetate of lime, research work was encouraged both in the universi-

ties and in the industry, and after laborious and painstaking investigations extending over many years, they were in a position to manufacture acetic acid and acetone from naturally occurring materials, namely, lime and coal, both available in large quantities in their own country.

#### SYNTHESIS FROM LIME AND COAL

Apart from a few experiments carried out by the writer while with the duPont Powder Company, nothing had been attempted in this country or Canada. However, the British Government was very fortunate in being able to obtain the hearty coöperation and assistance of the Shawinigan Light & Power Co., a Montreal corporation closely identified with the Canada Carbide Co. This concern on being approached by the British Government agreed to commence work immediately on the scientific aspect of the problem and was ably assisted in this connection by Prof. Ruttan of the McGill University, Montreal, Canada. They were fortunate in obtaining the services of Mr. Howard W. Matheson, formerly of the duPont Powder Co., and it is due to the chemical research investigations carried out by this chemist (ably supported as he was by the engineering skill of the vice-president of the company, Mr. Julian C. Smith) that they were successful within a period of one year not only in completing the experimental work (regarding which they were up to that time in complete ignorance), but also in erecting and starting the plant in actual operation.

The experimental work was started in December, 1915, and the plant was completed and commenced to operate in January, 1917, the total cost being somewhat over two million dollars. The output amounts to 56,000 pounds of 100 per cent acetic acid daily. When it is remembered that new and difficult questions of plant construction had to be faced, special type of construction relating to acid-proof materials and other important problems solved (in fact the creation of quite a new industry in this connection), and also that entirely new methods had to be devised in connection with each stage of the process, such as the electrolytic regeneration of the mercury etc., some idea may be obtained of the immense amount of labor involved. Not only was it necessary to build the chemical plant, but alongside of it a plant for the necessary calcium carbide had also to be erected and put into operation.

#### SECOND PLANT APPROACHING COMPLETION

When this country entered the war the question was discussed as to the advisability of erecting here a similar plant, but in view of the length of time it would take to develop the process and the saving which could be effected by coöperating with the Canadian Electro Products Co., an agreement was entered into for the duplication of the Canadian plant at an expenditure of over two million dollars. This second unit is now rapidly approaching completion and is expected to be in operation about December 1. The two plants will have an approximate production of around 55 tons per day of 100 per cent acetic acid.

The question as to what is to be done with this immense production after the war is one calling for serious consideration, as this is greater than the entire world's consumption. There would seem, however, to be no reason why the cost of manufacture should not

enable them to provide the industry with far cheaper acetic acid than was obtainable prior to 1914, and in this case the consumption will undoubtedly be largely increased in such industries as the manufacture of crude rubber, lacquers, dyestuffs etc. It should also be borne in mind that it is not at all improbable that extensive new industrial outlets will be found for acetaldehyde. This product, as far as its chemical reactivity is concerned may be said to bear the same importance to the so-called "aliphatic" chemical compounds as benzene does to the aromatic derivatives. From it by various chemical processes a whole series of valuable products

practically constant. Recent researches have shown that it is possible to submit the wood tar to a process of distillation and by this means separate out certain of its constituents possessing marked germicidal action. This special property may then be intensified to a remarkable extent by certain simple chemical processes, thus increasing the value materially for purposes such as wood preserving, disinfectants, sheep dips etc.

There would also appear to be no doubt but that certain fractions of wood tar may be used to great advantage in the manufacture of varnish compositions and coatings, similar to the phenol formaldehyde con-

THE CANADIAN ELECTRO PRODUCTS COMPANY

such as glycerine derivatives, solvents for nitro and acetyl cellulose, useful varnishes, camphor substitutes, synthetic rubber and numerous pharmaceutical products can be obtained, the development and exploitation of which will certainly follow on the conclusion of peace.

#### WOOD DISTILLATION INDUSTRY ON THE DEFENSE

It is evident from the above that the wood-distillation industry after the war will have to fight for its existence, as the price of acetone will undoubtedly fall to a low level. In all probability the price of acetic acid made from carbide will be such that it will be impossible for them to compete. There is, however, a "life saver" in the situation in that the industry possesses in acetone, crude acetone oils, and wood tar, a very valuable source of, as yet, undiscovered revenue. If the wood distillation industry will only enlist the services of the industrial chemist, they will find that acetone can be readily and cheaply transformed into valuable solvents for varnishes and nitrocellulose lacquers. Moreover, it can be employed for the manufacture of synthetic rubber and glycerine substitutes, the latter possessing properties comparable to those of the ordinary glycerine of commerce. From the wood tar itself the well-known beechwood creosote can be made, the demand for which is increasing rapidly, while the production has remained

practically constant. Recent researches have shown that it is possible to submit the wood tar to a process of distillation and by this means separate out certain of its constituents possessing marked germicidal action. This special property may then be intensified to a remarkable extent by certain simple chemical processes, thus increasing the value materially for purposes such as wood preserving, disinfectants, sheep dips etc.

There would also appear to be no doubt but that certain fractions of wood tar may be used to great advantage in the manufacture of varnish compositions and coatings, similar to the phenol formaldehyde con-

densation products, while the pitch obtained as a residue when manufactured under certain well defined conditions is found to possess properties rendering it much more valuable than ordinary coal tar pitch for certain insulating purposes. Furthermore, there is a wide field in the application of certain constituents of these oils for use as protective coatings in the lining of acid vats, as extended experiments would seem to indicate that corrosion could best be guarded against in the handling of large quantities of acid liquors of various kinds by the employment of such materials.

#### GERMANY AND SWITZERLAND MAKE ALCOHOL AND ACETIC ACID FROM CALCIUM CARBIDE

Nothing is clearer than the fact that unless the wood distillation industry awakens to the necessity of the employment of the trained research chemist and chemical engineer in the development of their business, the industry faces a very disastrous future. That this is the case is borne out by the fact that both in Germany and in Switzerland large electrical installations have been erected for the manufacture of alcohol and acetic acid from calcium carbide. The one in Switzerland is expected to use a minimum of 20,000 and a maximum of 30,000 hp. and produce annually 7500 tons of alcohol as a minimum and 10,000 as a maximum. It is stated

that this will make Switzerland an exporter instead of an importer of alcohol. The writer is informed by the American Consul in Berne, Switzerland, that the manufacture of acetic acid has already been commenced and that the manufacture of alcohol will be taken up later. In the Swiss Government reports on this subject, attention is drawn to the fact that Switzerland is dependent on this country and Austria-Hungary for its supply of acetate of lime. Government support for this undertaking was obtained with a view to making the country economically independent in this respect.

In Germany, according to the *Chemical Trade Journal*, the quantity of acetic acid produced in 608 vinegar factories amounted in 1913 to about 12,000 tons, while the quantity produced from calcium acetate and wood vinegar amounted to 23,000 tons of anhydrous acid. During the war several large factories for the production of acetate acid from carbide had been completed, while others are in course of construction with a view to the manufacture of artificial rubber. The factories if fully utilized are capable of producing 25,000 tons of acetic acid annually.

Much valuable research work has already been carried out under Government auspices at experimental stations such as the one at Madison, Wisconsin, and if full advantage were taken of these results as well as of the desirable coöperation of the industry, with such well equipped institutions as those at Syracuse, Cornell and Michigan, the future of the industry might be assured. As some of these institutions are supported by State funds, it is difficult to understand why their coöperation should not be sought and in fact insisted upon.

The article by Messrs. French & Withrow, referred to above, gives a very complete historical review and account of present day conditions in the wood distillation industry and contains much valuable food for thought in this connection.

New York City.

### Dyeing With Coal Tar Dyestuffs

By C. M. Whittaker. Pages, 214. Price \$1.80.  
London: Baillière, Tindall & Co.

The author has been in charge of the experimental dye-house of one of the larger British dye manufacturers for a number of years and while he has not undertaken to teach the novice to be a successful dye artist, he has made a great deal of information on this subject more interesting as well as easily capable of assimilation. The point of view throughout the book has been based on the commercial requirements. Basic dyestuffs are described with reasonable detail and the scope of use of this class of colors indicated. Acid dyes, alizarine, direct cotton, azo, resorcin, sulphur, vat, oxidation and compound textile dyes are all treated in a very readable manner.

Mr. Whittaker says, "The ever present demand for cheapness must always be recognized, however much one may regret it. Big production in modern industry takes the form of a cheap, not a dear, article. A constant endeavor is being made by cloth designers to make as good an imitation as possible of a costly fabric of a cheaper material. This explains why one now meets so many fabrics which contain wool and cotton to imitate at a low price the more expensive all-wool article. To give an example, a cotton warp is woven with a woolen weft in a serge pattern to imitate an all-woolen serge. These fabrics have to be dyed, and reflect themselves in the increasing demands for union dyestuffs, which has been one of the most striking features in the modern coal-tar dye industry." The subject of dyehouse machinery is not gone into, the book being intended to supplement the average chemist's training in preparation for textile work.

## The Manufacture of Enamel-Lined Apparatus\*

BY EMERSON P. POSTE

THE field of enameling includes enamels applied to steel and those applied to cast iron. Under the former heading we have cooking ware, signs and other miscellaneous pieces and apparatus used for large-scale food preparation and the chemical industries. Cast iron includes sanitary ware, various stove parts and other decorative pieces and apparatus for chemical and pharmaceutical purposes.

In the preparation of an enamel, various raw materials such as feldspar, borax, soda, cryolite and fluor-spar are used for the basis of the mixture. Various colors are produced by the use of cobalt, manganese and other coloring oxides some of which are added in the original mix and others in the mill.

These raw materials are thoroughly mixed and placed in a hot smelting furnace, where the materials are melted together and drawn out into a tank of water and granulated. The product is called frit. This frit is ground either wet in a pebble mill with water, clay and other mill additions, or ground in a dry mill for application by the dry process.

The steel ware to which the enamel is to be applied is manufactured either by pressing, drawing, spanning or welding. Whatever the manner of preparation or the nature of the piece, the surface to which the enamel is to be applied must be clean. This is accomplished either by pickling or sandblasting, depending upon the size.

The application of the enamel by the dry process on cast iron involves the spraying of a preliminary ground coat which when dry is placed in the furnace and withdrawn at a red heat. The dry powder is dusted on, the piece put back in the furnace, the enamel melted down, the piece withdrawn, more enamel added, and so on until a sufficient coat is built up.

In the wet process the enamel after drawing from the wet mill is treated with electrolytes to make a proper consistency for spraying or other method of application. The piece is then either dipped in the enamel, the enamel poured over or sprayed on, depending upon the size and shape of the piece.

In the burning of the ware two general types of furnaces are used, direct-fire and muffle. The latter is more general in connection with cooking ware and smaller pieces while the former is used on some of the larger pieces used for chemical work and large-scale food preparation. In either case the burning of the enamel consists in melting down the individual particles and fusing them together in the form of a continuous coating.

Apparatus made in accordance with the above general outline ranges from 50-gallon to 4500-gallon units in steel and from 2-gallon to 300-gallon in cast iron. The former line finds application primarily in the dairy, canning and other food industries. Units are also used as storage, evaporating and reaction tanks for chemical processes of a neutral or slightly acid nature. The cast iron equipment is used as above and in addition for the most severe chemical conditions involving mineral acids.

\*An abstract of a paper read at the Fourth National Exposition of Chemical Industries, New York, Sept. 24, 1918. The paper was illustrated by lantern slides, and there was an exhibit of products.

# American Dyes from a Manufacturing Standpoint

Domestic Dyestuff Industry Becoming an Accomplished Fact—Analysis of Our Needs and Figures of Actual Production—Permanence of Industry Depends on Tariff

By W. H. WATKINS

THE developments growing out of the Great War made it evident by the Spring of 1915 that we should be obliged to look to ourselves for our accustomed supply of dyestuffs. There was no question of going without them. The great textile, leather, paper and other industries were in great part dependent upon dyes for the production of merchantable goods. Natural dyestuffs found in part fill the gap caused by the elimination of Germany as a source of supply of coal-tar dyes; but natural dyestuffs could not be obtained in sufficient quantity, nor were they in many cases acceptable substitutes either by reason of lack of fastness or variety of hue, or because of difficulty of application. If the textile, paper, leather and other industries giving employment to perhaps two million people and producing goods of a value of perhaps four billion dollars were to continue doing "business as usual" an American coal-tar dyestuff industry had to be created.

To the chemist the outlook was most enticing. What could be finer than the opportunity for working out methods for the manufacture of hundreds, perhaps thousands of beautiful compounds, beautiful to the chemical sense as well as to the eye. The manufacturer, chemist or not, who contemplated engaging in this industry however, could not consider alone the alluring chemical side of the problem. American chemists had always found this coal-tar chemical industry a most interesting industry to look at and talk about, but also had generally concluded that it was a very safe industry to let alone. The few chemists or manufacturers who did take hold of it were generally found after a few months, or a year or two, vigorously blowing their fingers.

## FIGURES AND STATISTICS NOT ALLURING

So it was well for the manufacturer who felt the lure of coal-tar dyes or chemicals to look over the chemical charts before embarking on the deep waters of their manufacture. The most recent charts available in the spring of 1915 were not particularly encouraging. An eminent ex-president of the American Chemical Society had demonstrated to the United States Chamber of Commerce that it was distinctly a "one-nation" business. He made a good case of it too. He showed that the import value of the coal-tar chemicals used in the United States was less than the value of the confectionery sold over the 5- & 10-cent counters.

Our most eminent student of chemical statistics in a most comprehensive study pointed out the complexity of the industry and its difficulties, and concluded that we could have the industry if we were willing to pay the price. The question the manufacturer had to ask himself was: Who is to pay the price?

The would-be manufacturer also found that the duty-paid value of the coal-tar dyes and chemicals, assuming the adoption of the highest duties to be hoped for, would not be over \$15,000,000 per year on the basis of pre-war values. He further found according to authoritative statements that 922 different dyes were necessary, these being dependent upon about 300 intermediates made from ten coal-tar crudes by the use of vast quantities of acids, alkalies and other chemicals.

The business had a pot-walloping look at the best, and the American genius for production has not been of the pot-walloping order. However, the statement in regard to 922 dyes referred to above was based on the number of dyes listed in the 1914 edition of the *Schultz-Tabellen* and not on an analysis of the American dyestuff problem as it existed.

## FORMULATING THE REAL PROBLEM

The problem for solution by the American dyestuff manufacturer might have been stated somewhat as follows: To provide such a line of coal-tar dyes as in variety of hue, method of application, and fastness, will meet the needs of the textile and other manufacturers in these respects, having in mind the requirements of the ultimate consumer for service on the one hand, and the exigencies of manufacture on the other.

An analysis of the problem so stated made it seem possible to meet the legitimate demands of the situation with about 300 dyes derived from about 100 intermediates. Further analysis seemed to indicate that it might be possible to put the main part of the business on something better than a pot-walloping basis. If the industry is to be carried on by a large number of small concerns however, each endeavoring to bring out a complete line, it will be a business of small units and high labor costs.

In the following analysis the estimated needs of the whole country for the volume and kind of manufacture carried on before the war, has been taken as the basis.

The war conditions of today, however, have "busted the whole plan of salvation." But the war must be over some day, and the manufacturer who would survive must look forward to that day as well as take care of the emergency needs of the present.

## ANALYSIS OF UNITED STATES' DYE NEEDS

An annual American consumption of 50,000,000 lb. of coal-tar dyestuff has been assumed, and the information disclosed by the "Norton census" has been applied to the original estimates.

The necessary dyes were placed in five classes according to the quantities needed annually.

First Class.—Consumption in excess of 1,000,000 lb.

per year. Eight dyes fell in this class with a total of 25,000,000 lb. or one-half of the whole.

Second Class.—Consumption less than 1,000,000 lb. but 250,000 lb. or more. Twenty-seven dyes fell in this class with a total of 10,500,000 lb.

Third Class.—Consumption from 100,000 to 250,000 lb. Fifty-one dyes fell in this class with a total of 7,100,000 lb.

Fourth Class.—Consumption from 50,000 to 100,000 lb. Forty-seven dyes fell in this class with a total of 3,200,000 lb.

Fifth Class.—Consumption less than 50,000 lb. Approximately one hundred and sixty dyes would fall in this class with a total of 4,200,000 lb. or about 25,000 lb. each on an average.

So unless production of the same dyes was undertaken by too many independent concerns, a good part of the dyestuff manufacture could be put on a respectable production basis; that is, advantage could be taken of labor-saving devices and materials could be routed with some degree of order and system.

#### CHEMICAL PROBLEMS IN PRODUCING INTERMEDIATES

But there is another and more complex feature of the problem. To make these dyes the intermediates must first be made. We may estimate that our program will call for 100,000 lb. of an ortho isomer and find that in producing that amount of ortho we also get 200,000 lb. of the para isomer for which we have very little outlet. The ultimate success of the American dyestuff industry will depend largely upon the correct solution of just such problems. The solution of such problems will inevitably compel the manufacturer who would limit his business to a few individual dyes to increase his line, and increase will bring additional problems. But the manufacturer who piles up his para in order to sell ortho will certainly burn his fingers if he sticks to it.

Assuming that the 300-dye program is reasonably correct, the present status of the industry is encouraging. The estimate of the present status as here given is not based on the manufacture of any one concern but on the entire production of the country as far as it can be gaged by the products now on the market. The figures given below should not be taken as absolute. They are, however, approximately correct.

#### OUR PRESENT PRODUCTION OF DYES

Of the eight dyes placed in class 1, seven are being made now, in several cases in amounts considerably in excess of the original estimates.

Of the twenty-seven dyes in class 2, nineteen are now on the market and plants for the remaining eight are already in process of construction or projected.

Of the fifty-one dyes in class 3, twenty-six are now on the market and plants for nineteen of these remaining are being constructed or projected.

Of the forty-seven dyes in class 4, seventeen are now on the market and of the remaining thirty, plants are either under construction or projected for fifteen.

Of the large number of dyes in class 5, about sixty are on the market and sixteen are in prospect.

Not all the dyes mentioned as on the market are there in sufficient amounts, but if they can be made, it is only a question of increased plant to produce them

in sufficiency. The main problem as far as they are concerned has been solved, provided some inconvenient, not to be disposed of, isomer does not enter into consideration.

#### DEVELOPMENT IS PROCEEDING LOGICALLY

It is evident that the development of the American industry has proceeded on correct lines from the standpoint of the interest of all concerned. Those dyes required in largest amounts have actually been made first, and new projects have been undertaken roughly in the order of their importance as measured by the amount consumed.

This perfectly correct policy, however, has made it necessary to delay the production of some dyes, the importance of which is not measured entirely by the amount consumed. These dyes are those requiring comparatively small amounts of special intermediates. Obviously, such dyes require quite as much chemical and engineering investigation as those needed in larger quantities. It has certainly been the wisest course to apply the available chemical and engineering skill in such a way as to have it result in the production of the greatest possible amount of the commodities dependent upon dyes. The problems already solved also have their application in the solution of those as yet unsolved. There are few types of reaction employed in manufacturing dyes with which American chemists and engineers are not now familiar. The remaining problems, therefore, present fewer difficulties than the earlier ones. Then, too, many of the dyes needed in comparatively small amounts will appear simultaneously with dyes of greater importance, as the intermediate necessary for an important dye is frequently the one intermediate lacking for the production of a number of less importance.

With a few gaps here and there, the needs for acid, basic, chrome, and direct dyes are fairly well met with the dyes now available. With those in prospect, practically all needs will be satisfied for these classes.

#### QUALITY OF DOMESTIC PRODUCT EQUAL TO IMPORTED

Well-established American dyes made today by recognized manufacturers are equal in quality to the same dyes as formerly made in Germany. It is true that a considerable number of dyes formerly made in Germany are not as yet made in America. The lack of these dyes is partly responsible for the lack of fastness to light and wear being sometimes observable in textile fabrics. As a rule, however, such lack of fastness is due to faulty application, or to the wrong choice of available dyes for the job in hand.

Alizarin has appeared and its derivatives will follow. Vat dyes will not be long delayed. With good fortune, including a reasonable supply of chemists, labor, acids, toluol and phenol, the next year should see the American dyestuff industry a complete, accomplished fact.

Important as the establishment of this industry is for America, it is much more important that the war be won. Many of the essentials for making dyes are also essential for maintaining the military establishment, and the military establishment comes first. As between chrysophenine and TNT there is but one choice. So it may be safer to say that, subject to winning the

war, the next year will see the American dyestuff industry an accomplished fact.

The permanence of the industry is another matter. With Germany able after the war to lay goods on the dock in New York at pre-war prices, its permanence may be doubtful under existing tariffs. America has been shown that she can have a dyestuff industry at a price. What this price in the way of tariff protection may be no one can now estimate. But America knows the price she has paid for the lack of a dyestuff industry and will undoubtedly be willing to pay the price to keep the one she has gained.

American dyestuff manufacturers appear to be proceeding as though assured of a permanent industry.

Buffalo, N. Y.

## Ordnance Department Establishes Industrial Education Section

The Army Ordnance Department announces the establishment of an Industrial Education Section for the purpose of increasing productive efforts in the plants engaged in the manufacture of ordnance material.

The activities of the section are under the direction of Major F. L. Thompson and Captain C. R. Dickinson, and will be aimed to carry home to the individual worker, be he employer or employee, the fact that his own personal efforts will have a direct bearing on the winning of the war. The agencies employed include posters, booklets, pay-envelop stuffers, newspaper publicity, display advertising, motion pictures, public speakers and exhibits.

Posters carrying a message of encouragement to the worker tending to inspire greater individual effort are sent out to the manufacturing plants at regular intervals. Some of these, notably "Not Just Hats Off to the Flag, But Sleeves Up for It," have been remarkably successful, according to the more than 900 letters received by the Ordnance Department regarding it.

Booklets and pay-envelop stuffers are used to convey inspirational messages to the home and thereby tend to increase the morale of the community. An edition of 2,000,000 of one of the smallest posters ever issued, bearing a message to the individual, was distributed in a number of cities on Labor Day by means of aeroplanes dropping them over the course of the parade.

In the neighborhood of 1000 plants working on war materials now have motion-picture projection rooms and have been furnished films with a distinct appeal to the worker, such as the Government films, "Pershing's Crusaders" and "America's Answer." These films have proved very successful in definitely linking up the work of the man at the lathe with the boys at the front.

In the same manner, speakers, many of them foreign soldiers returned from the front, have been furnished to meetings of plant employees, and have given their hearers first hand information as to how necessary it is to speed up production.

Advertising and publicity in the newspapers by local communities has been advocated and copy furnished from Washington whenever desired.

In some instances, it has been found desirable to encourage public exhibitions of locally made material

used by the army as a means of arousing local pride and stimulating interest in war work. Several exhibitions of this kind illustrating the use to which the material was put in actual service, have been the direct means of increasing the pride of the citizens in their town and consequently in their own work.

In order to centralize the work and afford increased service to the various war working plants, it has been decided to appoint a representative of the Industrial Education Section in each of the eleven District Ordnance Offices as follows:

Bridgeport, Conn., Ralph B. Boas, formerly instructor at Brown and Harvard universities and a writer and lecturer of note; Boston, D. D. Cassidy, architect; New York, Major J. C. Mitchell, U.S.A., formerly president Etheride & Company, advertising agency; Philadelphia, J. W. Watson, president of the American Bronze Company; Rochester, N. Y., William H. Complice, Rochester Chamber of Commerce; Pittsburgh, Charles Yon, Pittsburgh & Lake Erie Railroad; Detroit, W. G. Pipp, editor *Detroit News*; Cincinnati, Carl H. Jacobs, Jr., vice-mayor and former assistant city solicitor; Chicago, D. L. Benjamin, of Gray & Benjamin, advertising agents; St. Louis, Homer Hall, assistant district attorney. The representative for the Cleveland district has not as yet been appointed.

These men are to be responsible in their respective sections for the activities of the Industrial Education Section which will act as a service agency at the disposal of the various District Ordnance Chiefs to assist them in increasing production effort.

## Chemically Treated Fabrics for Powder Bags

Chemically treated cotton cloth, as a substitute for silk, is being tested out by the Ordnance Department. If found practicable for ordnance uses, the discovery will effect the double result of meeting a serious shortage in silk, and of bringing about a money saving in the ordnance program estimated at between \$25,000,000 and \$35,000,000.

Preliminary tests already made at the Aberdeen Proving Grounds have encouraged the department to proceed further with its experiments; and for this purpose an order for 5,000 yards of the new material has been placed with the concern responsible for developing the process of treating the cotton cloth.

At present millions of yards of silk are required in making the bags which contain the large powder charges used in the firing of heavy artillery. These bags are inserted in the gun immediately behind the projectile, and the firing of them gives the propelling force that hurls the projectile at the target. This propelling charge is, of course, entirely distinct from the charge within the projectile that explodes the missile after it reaches the target.

Hitherto silk has been depended upon for these bags for the reason that no other cloth material has been found that would meet the peculiar conditions required. It is essential that not a particle of the bag container shall remain after the gun is fired. Otherwise a smouldering piece of the fabric might cause a premature explosion when a new charge was inserted.

# Large-Scale Sulphuric Acid Manufacture

A Description of the Plant of the Tennessee Copper Company Where the Special Features in Both Construction and Chamber Control Are as Noteworthy As the Fact that This Plant Is the Largest in the World

BY ANDREW M. FAIRLIE

Consulting Chemical Engineer, Copperhill, Tenn.

THE large plant for the manufacture of sulphuric acid may consist of either a large number of small or average units, all located at a single site and operated under one management, or a few units of unusually large proportions. In the former case the equipment and methods of operation need present nothing of extraordinary interest. The chambers, towers, fans, blow-cases, etc., may all be of a type and size with which the average acid-maker is familiar, and the operation of a number of small plants presents no difficulties or unusual situations which are not encountered in the operation of a single small plant.

An example of a large plant composed of a large number of units will be the new sulphuric acid plant now being erected for the U. S. Government at Brunswick, Ga. This plant will consist of eight units, each of 100 tons capacity. A 100-ton unit was formerly considered a large plant, but now that there are in this country so many units two or three times that size, the 100-ton unit has almost shrunk to average size by comparison. Another large plant, consisting of a large number of small units, is the plant of the United States Steel Corporation at Donora, Pa. This plant, comprising six units, each of 75 tons capacity, has a total capacity of 450 tons daily. Such plants as these, being a multiplicity of small or average units assembled or constructed at one site, contain presumably only the usual equipment, common to plants of average size anywhere.

## THE PLANT OF THE TENNESSEE COPPER COMPANY

It is the large plant composed of one or more extra large units that presents features of more than ordinary interest. The plant of the Tennessee Copper Company, located on the Ocoee River in the southeastern corner of Tennessee, is recognized as being not only the largest sulphuric acid plant in the world, but as being composed of the largest units in the world. The Tennessee Copper Company enjoys the distinction of being the original pioneer in the manufacture of sulphuric acid by the chamber process from the waste fumes of copper blast-furnaces. It is indeed fortunate that years ago the difficulties at first encountered were overcome, and that long before 1914 the enterprise had been put on a permanent and reliable basis, so that now, when acid is so much needed, and when sulphur and pyrites are so scarce, this large supply of sulphuric acid, made as a by-product, may be forthcoming to meet the needs of the Government.

The sulphuric acid plant of the Tennessee Copper Company comprises Plant No. 1 and Plant No. 2. Plant No. 1 is composed of two units, each of an average

daily capacity of 300 tons (60 degrees Baumé). These two units were formerly a single unit of 600 tons daily capacity, but in 1917 this large unit was subdivided into two approximately equal units. No. 2 Plant consists of one unit only, of a capacity of approximately 300 tons.

The five prominent features of a sulphuric acid plant are the burners, for generating the sulphur dioxide gas; the niter pots or retorts, for generating the oxides of nitrogen from nitrate of soda; the Glover tower, for denitrating the nitrous vitriol, concentrating the chamber acid, furnishing a part of the steam for the chambers, and cooling the hot burner gases; the lead chambers, the oxidizing, hydrating, and condensing apparatus; and the Gay-Lussac towers, for recovering the oxides of nitrogen in the form of nitrous vitriol. Less prominent, but quite as important features, are the gas fans, the acid pumps or blow-cases, the acid coolers, the hydration supply system, and the tanks.

The plant of the Tennessee Copper Company has no burners. The sulphur dioxide gas is generated in the copper blast-furnaces, and is conducted through a large brick flue to the Glover towers. This flue, the cross-sectional area of which is 200 square feet, is over 200 feet long to No. 1 Plant, and more than 500 feet long to No. 2 Plant. The percentage of sulphur dioxide in the gases ranges usually between 3 per cent and 6 per cent and the temperature of the gases entering the Glover tower may range between 600 and 900 deg. Fahr.

## EXTERNAL NITER RETORTS AND AUTOMATIC CHARGERS

The niter retort system now in use at these plants is unique. The common method of "potting" niter is to have the pots inside the hot-gas flue leading to the Glover tower, and to rely on the heat of the burner or furnace gases to distil the niter fumes from the pots. This method was formerly used at the No. 1 Plant of the Tennessee Copper Company. But it was found that some portion of the charge would overflow the pots, and from time to time a pot would develop a leak, permitting some of the charge to run out of the pot; and though due provision was made for tapping out such molten overflow or leakage from the pans underneath the pots, nevertheless, some of the overflow and leakage would inevitably solidify inside the hot-gas flue. Crusts of solid niter cake inside the flue would grow in size, until in course of time a solid mass would be formed in the flue, thus partially blocking the flue for the passage of gas and preventing the gas from getting free access to the pots in order to heat them, so that under these conditions it was neces-

sary to shut down the entire plant, once or twice a year, for ten days or more, in order to clean the niter cake out of these flues.

For this reason the pots inside the flue were abandoned, and a system of retorts outside the flue and fired with coal was installed. The retort adopted is the standard retort used in nitric acid manufacture, and is shown in Fig. 1.

This retort is ten feet high and eight feet in diameter, and is large enough to cook a charge of 8000 pounds of nitrate of soda without overflowing. The retorts are built in groups of three retorts to a chamber unit, but usually two retorts are sufficient to operate a unit, the third being held in reserve as a spare. Fig. 2 shows one of these groups of retorts.

Each retort is supplied with niter by an automatic feed device, motor-driven, and geared to a lead wheel provided with lead cups burned to its circumference, revolving in a small tank of acid in unison with the

FIG. 1.—RETORT

revolutions of the worm which feeds the niter, so that automatically, as the niter is fed, the correct proportion of sulphuric acid is poured into the pot. Fig. 3 shows a close-up view of this mechanical feed for niter and acid.

The Glover towers of these plants are octagonal in shape, are 55 feet high and 30 feet in diameter from lead to lead. The lead curtains are lined with chemic 1 brick laid in acid-proof cement. The thickness of the brick walls at the bottom of the tower is  $22\frac{1}{2}$  in. The towers are packed with acid-proof tile. The amount of acid pumped over the three towers, combined, including nitrous vitriol and chamber acid, is about 3600 tons, or 72 tank car loads per day. The chamber acid is concentrated to a strength of about 60 deg. Bé. The temperature of the acid discharged from the Glover tower is about 280 to 300 deg. F., and of the gas escaping from the tower into the chambers, about 200. feet high, four chambers 22 x 50 x 77 feet high, four

#### SIX MILLION CUBIC FEET OF CHAMBERS

The lead chambers at No. 1 Plant are 34 in number, and are of unusual height. There are eleven chambers, 50 x 50 x 67 feet high, six chambers 50 x 50 x 72

chambers 18 x 50 x 77 feet high, four chambers 10 x 50 x 67 feet high, and five chambers 67 feet high, but of varying lengths and breadths. The total chamber space at No. 1 Plant is 3,944,800 cu.ft. At No. 2 Plant there are only four chambers altogether, but these are probably the largest acid chambers ever built. The dimensions are 59 ft. wide x 236 ft. long x 40 ft. high, each chamber enclosing 556,960 cu.ft. of space.

FIG. 2.—NITER RETORT GROUP

The total chamber space at No. 2 Plant is 2,227,840 cu.ft. For both plants combined the total chamber space is 6,172,640 cu.ft. At No. 1 Plant the chambers are connected by straight flues, these flues being alternately at the tops and bottoms of adjoining chambers. As most of the alleys between the chambers are only seven feet wide, most of the chamber connections are quite short. An exception to this rule is the flue con-

FIG. 3.—AUTOMATIC FEED

necting No. 6-B chamber with No. 7-B. These two chambers are so located that they are about 225 feet apart, and it was necessary to build a special flue to connect them. This flue, octagonal in shape and having a cross-sectional area of 100 sq.ft. and a diameter of 11 ft., has become quite famous throughout the country as the flue "big enough to drive an automobile through"—which is literally true of it. This flue has been referred to sometimes as the "Zeppelin Flue," from its resemblance to a Zeppelin airship. It is shown in part in Fig. 4, and its size looms large in comparison with the man standing beside it. The cross-sectional area of the other chamber connections at No. 1 Plant is approximately 100 sq.ft.

At No. 2 Plant the connections between the chambers are usually only seven feet long. But here each pair of adjoining chambers is connected by two connections (instead of by one only as at No. 1 Plant), each with a cross-sectional area of 25 sq.ft. There is one long, round flue, connecting the east side of No. 2 chamber with the west side of No. 3, by means of a return bend, whose diameter is 5 ft. 9 in.

#### SPECIAL SYSTEM OF GAS MIXTURE CONTROL

The chambers at both plants are provided with the usual equipment of thermometers and hydrometers for regulating the chamber temperatures and the strength of the "drips." While these instruments are used as aids in the control of the process, the quantity of niter admitted to the plant is regulated in accordance with the indications of the analytical method of chamber process control, originated by the author at this plant in 1910, and in continuous use there ever since.<sup>1</sup> This method of control has proved very useful at these

FIG. 4.—SULPHUR DIOXIDE FLUE

plants, on account of the fluctuating character of the furnace gases, and its use has resulted in a large saving of nitrate of soda. The method was described in detail in the *Transactions of the American Institute of Chemical Engineers*, Vol. IX (1916), pp. 319-332, and for a complete understanding of the method, the reader should refer to this publication.

Briefly, the method consists in the establishment, as the result of experiment, of a series of desirable ratios between the percentage of sulphur dioxide in the gas entering the Glover tower and the percentage of sulphur dioxide in the gas mixture at any fixed point in the front chamber, covering the entire range of sulphur dioxide percentages which are likely to be encountered; and in maintaining thereafter such desirable ratios constantly, by introducing the right amount of nitrate of soda for the purpose. Once the series of desirable ratios is established, they are arranged in tabular form, and the table is framed and posted before the eye of the chamberman. This man tests frequently the percentage of sulphur dioxide in the gas at the point in the front chamber chosen for the test, and by comparison with the percentage of sulphur dioxide in the gas entering the Glover tower at about the same time, knows by reference to the established table whether the amount of niter going into the system is too little,

too much, or just right. If any error in the amount is made, the error is detected in the front chamber, and the mistake is corrected before any serious damage is done. By this means it is possible to maintain uniformly the desirable percentage of sulphur dioxide in the gases escaping from the last chamber (from 0.06 to 0.12 per cent under normal conditions) thus securing the most efficient recovery of nitrous oxides in the Gay-Lussac tower.

#### TWO TYPES OF GAY-LUSSAC TOWERS

The Gay-Lussac towers at No. 1 Plant are eleven in number, and are of various shapes and sizes. Three of these towers, octagonal in shape, are 62 ft. 4 in. high and 35 ft. 7 in. in diameter from lead to lead; four smaller towers, also octagonal, are 70 ft. high and 19 ft. in diameter from lead to lead; and four square towers are 47 ft. high and 23 ft. square. These towers have lead curtains, lined with acid-proof brick walls laid dry; some are packed with quartz, and others with acid-proof brick or tile.

At No. 2 Plant the Gay-Lussac tower is of peculiar construction. There is only one tower, and it is built of acid-proof brick laid in acid-proof cement, without lead curtains. The tower is divided into 56 cells or compartments, the partitions being of acid-proof brick. The arrangement of the compartments is eight parallel rows of cells, seven cells to the row. The gases traverse the eight rows in parallel, and pass up one cell and down the next (and so on) of each row, until, arriving at the top of the seventh cell, they are drawn through the back fan and are then expelled through the exit stack into the atmosphere. The cells are each eight feet square inside, with a total height of 40 ft. They are packed with acid proof tile laid on edge. The distribution of the acid over the tops of the cells is effected by means of a single acid feed-pipe to each cell, terminating in a sprayer provided with a splash-plate inside the tower, by means of which the acid is quite evenly sprinkled over the entire top of the tower packing. The lead pan at the bottom of the tower is divided into three compartments by means of brick partitions, whereby it is possible to keep separate nitrous acid of three different grades of nitrosity, as discharged from the tower. The effect, then, of this peculiar tower, so far as the feed and discharge of the acid is concerned, is that of three towers arranged in series—the first (the one nearest to the chambers) consisting of eight rows of three cells to the row, over which the acid discharged from the middle group is fed, and from which the nitrous vitriol which is fed to the Glover top is obtained; the second, consisting of a continuation of the same eight rows, but with only two cells to the row, on which the acid discharge from the last group of cells is fed; and the third, consisting again of a continuation of the same eight rows of cells, two cells to the row, over which cooled acid discharged from the Glover tower is sprayed. This Gay-Lussac tower, or cluster of little towers, is of interest because of its peculiarity. After two years of operation, no particular advantage in this type of tower has been observed, but serious obstacles or disadvantages have been encountered, chief among which is the difficulty of washing the cells when they become clogged with acid sediment.

<sup>1</sup>See U. S. Patents, Nos. 1,205,723 and 1,205,724.

An unusual quantity of sediment is deposited from the acid made at these plants. This is because of the flue-dust blown out of the furnaces by the blast. At the ordinary plant, air is admitted to the burners or furnaces in a natural way, as induced by the draft of the acid plant. But in the case of the copper blast-furnaces air is blown into the tuyeres at the bottom

FIG. 5.—IMPELLER FOR  $\text{SO}_2$  GAS

of the furnaces under a pressure of about four pounds per square inch. This blast inevitably forces large quantities of fine particles of the furnace charge out of the furnace, and although brick chambers have been provided for settling the dust before the gas reaches the Glover tower, a substantial quantity of the finer dust enters the Glover tower with the gas, and encountering there the streams of acid flowing down the tower, is washed out, to form a stiff paste which collects at the bottom of the tanks. But not all of the solid impurities are eliminated from the gases, even in the Glover tower. Zinc fume, in particles so fine as to escape being washed out by the generous streams of acid pouring down the Glover tower, finds its way through the tower packing into the lead flues leading to the gas fans, and in the fans most of it is deposited as impure zinc sulphate, partly in the bottom of the fan casing, and partly on the vanes or blades of the impeller. A part of the zinc fume even goes on past the fan, to be deposited as zinc sulphate in the bottom of the chambers.

#### GASES PROPELLED WITH LEAD-ANTIMONY BLOWERS

As would be expected, the furnace blast produces a pressure on the hot-gas flues. This pressure is not sufficient, however, to force the gas through the chambers at the desired rate of speed; and moreover if reliance were placed exclusively on the furnace blast as motive power for the gases, the pressure on the hot-gas flues and on the furnace tops would be so great that not only would a large proportion of the gases be lost, but conditions on the furnace charge floor would be intolerable for the smelter workmen. Gas fans, therefore, have been installed for the purpose of drawing up the gases from the furnaces, and forcing them

on through the chambers. Gas fans are a common, and, indeed, a necessary adjunct, of any modern acid plant, but are usually much smaller in size than the fans about to be described.

The impellers of these fans, made of antimonial lead, are eight feet in diameter, and the vanes, of which there are ten to each impeller, are four feet wide. The vanes are attached to the hub by means of twenty cast arms or spokes. Keyed to the cast lead hub there is an inner hub of cast iron, and to this the steel shaft is keyed. The complete impeller, including shaft, cast-iron hub, lead hub, arms, vanes and shields, weighs approximately six tons. These impellers are made at the shops of the Tennessee Copper Company, and several have been made there for some of the large plants of the far West, which use this type of gas fan. Fig. 5 shows this impeller, and Fig. 6 shows the external appearance of one of these gas fans, the impeller being concealed by the housing.

#### BLOW-CASES SUPERIOR TO OTHER ELEVATING DEVICES

At No. 1 Plant seven of these fans are in operation, four at the front end of the chamber system and three at the back. At No. 2 Plant there are two front fans and two back fans.

Various means of pumping acid have been tried at these plants—blow-cases, electrically-driven centrifugal pumps (both horizontal and vertical types), electrically-

FIG. 6.—GAS FAN

operated skip-hoists, and air-lifts, and while some of the newer devices for elevating acid have shown lower costs than blow-cases as regards power consumption, from the standpoint of efficiency, operating labor required per unit of acid pumped, cost for repairs, total operating cost, and freedom from interruptions, no elevating device tried has equalled the compressed-air blow-case. For this reason all acid pumping done at these plants, with the exception of the elevating of the chamber acid (for which the air-lift is used) is now

done by means of blow-cases. The blow-case usually met with at an acid plant is made of cast iron; but at these plants blow-cases made of riveted wrought iron plates were adopted ten years ago, and have proved so successful that there has never been a cast-iron "egg" for pumping sulphuric acid on the place. The feed lines to these blow-cases are 6-inch iron pipes, and the discharge lines are 4-inch iron pipes.

Necessarily, for the purpose of cooling the enormous quantity of acid discharged from the Glover towers of these plants, coolers of special design had to be constructed. At No. 1 Plant there are six coolers, rectangular in shape, the inside dimensions being 17 ft. long x 8 ft. 6 in. wide x 4 ft. 8 in. deep. The frame-work is of steel channels placed edgewise to the cooler, supporting a shell of 15-lb. lead, which is lined with 9 inches of acid-proof brick laid in acid-proof cement. Each cooler contains 71 coils of 1½-in. lead pipe, the coils being 12 inches in diameter. In the six coolers combined there are over four miles of 1½-in. lead pipe. Three of these coolers are built in terrace form so that the acid flows by gravity from one cooler to the next, and this is found to be an advantageous arrangement. At No. 2 Plant there are three coolers of the same type and size as those at No. 1. By means of these coolers the Glover tower acid is cooled from about 280-300 deg. to 100-110 deg. F.

#### ATOMIZED WATER USED IN CHAMBERS IN PLACE OF STEAM

The hydration of the acid in the chambers of these plants was formerly accomplished by means of steam. Water sprayers had seemed out of the question on account of the limited capacity of the sprayers on the market. An enormous number of these low-capacity sprayers would have been required to supply the quantity of water needed for the large-scale operations here under way. A special atomizer has been developed at this plant, however, capable of atomizing as much as fifty gallons of water per hour, and with this device water-spray has been substituted for steam in most of the chambers, resulting in a considerable saving in coal, lower temperatures in the chambers, larger chamber capacity, and apparently some saving in niter consumption. As the water for the sprayer is pumped by means of centrifugal pumps operated by electrical motors driven by water-generated current, the saving of the coal formerly used to generate steam for the chambers is complete.

#### WROUGHT-IRON BLOW-CASES AND TANKS BEING INSTALLED

The factory tanks at No. 1 Plant have been, until lately, of the usual wooden construction, lead-lined. When No. 2 Plant was built, in 1916, on account of the acid-resisting properties exhibited by the wrought-iron blow-cases, it was decided to try wrought-iron factory tanks. Accordingly, all of the tanks serving as acid reservoirs at the tops and bottoms of the towers, with the exception of one wooden lead-lined tank at the top of the Glover tower for chamber acid, were made of wrought iron. Two years service has proved that the experiment was justified, as the repair account for these tanks has been practically nil, and caliper measurements of the thickness of the iron shows that the

tanks have still some years to live. At No. 1 Plant, as the wooden lead-lined tanks become unserviceable, they are being replaced by iron tanks.

The storage tanks for these plants have been placed at such an elevation (with the exception of one tank) that the acid flows to them from the plant by gravity. These tanks are made of steel or wrought iron. The total storage capacity, including two tanks of 5000 tons capacity each, is 23,000 tons.

From the storage tanks the acid flows by gravity into tank cars for shipment, and with the clamping of the lid on the dome of the car, and the pasting of the diamond-shaped label on the sides and ends, the work of making a carload of acid is finished.

But while the work, with reference to any particular tank-car of acid, may be considered completed with the shipping of the car, the work of the acid-maker goes on in a cycle as endless as the flow of Glover acid to the Gay-Lussac top, down the Gay-Lussac tower to its bottom, thence as nitrous vitriol up to the Glover top, and down that tower back to the bottom, appearing again as Glover acid.

### Resumption of Sulphur Production

Advices to the Chemicals Division of the War Industries Board are that mining operations have been resumed in part at the plant of the Union Sulphur Company, at Sulphur, La., where considerable damage was done by the hurricane that swept over that region on August 6. Shipments of sulphur were resumed last week from the accumulated stocks and rapid progress is being made in the work of restoring normal conditions. Considerable rebuilding will have to be done but ample material is on hand for the work.

The company carried immense reserves of sulphur above ground so that there will be no interruption in the manufacture of sulphuric acid and other necessary war materials. This reserve pile of the Union Sulphur Company measures 800 feet in length by 200 feet in width, 40 feet high, and represents about fifteen months' mining.

The plant of the Freeport Sulphur Company at Freeport, Texas, is producing its normal tonnage and has a considerable reserve above ground. While the damage to the Union Sulphur Company is unfortunate, especially at this time when sulphuric acid is being produced in such an enormous way, the reserve stock situation is such that there is no cause for worry. The Union Sulphur Company's operatives are working day and night in the rebuilding of their plant. The sulphur is melted in the ground by steam and hot water and forced to the surface where the molten sulphur solidifies on exposure to the air. The sulphur deposit underlies a bed of quicksand through which it is impossible to drive shafts and mine in the ordinary way. The development of this project is one of the interesting mechanical and chemical achievements of the past decade and, together with the Freeport Company's development, makes the United States by far the greatest producer of sulphur. There are two other known deposits which can be quickly opened in case of necessity. Work is now progressing on the development of one of these deposits.

## Dyes from the Manufacturers' Standpoint

**American Dye Makers Have Made Remarkable Progress in Furnishing Types of Dyes Formerly Imported—Lack of Variety of Intermediates Responsible for Failure Thus Far to Manufacture All the Dyes Desired**

By LOUIS JOSEPH MATOS, Ph.D.  
Chemist National Aniline & Chemical Company, Inc.

WHILE coal-tar dyes have been manufactured in the United States for many years, it has only been since the outbreak of the war that it can truly be said that dyes of strictly American origin have been produced. This point has been referred to many times by other writers, who drew attention to the fact that we do not have in this country the so-called industry of the intermediates from which American dye makers could draw their initial supplies. As a consequence, such dyes as were made in the United States were necessarily produced from intermediates that had been regularly imported from Germany.

When the war broke out, and the stocks on hand of imported and such domestic dyes as were finished were becoming rapidly depleted, the necessity arose compelling the production of intermediates from domestic raw materials and this production has gradually increased until the present time, when quite a respectable number of such commodities are now available. For some few years prior to the war aniline had been regularly manufactured at the plant of the Benzol Products Company, now the Benzol Works of the National Aniline & Chemical Co. Inc., but, it was not until after the war that secondary products, derivatives of aniline, were seriously contemplated.

Naturally in the manufacture of dyes to meet commercial conditions the manufacturers, of course, took up the production of those coloring matters that could be most readily prepared from easily manufactured intermediates, for it must be remembered that with a few given intermediates it is possible to produce quite an additional number of finished dyes. With crudes being rapidly absorbed by the explosive industry the manufacture of intermediates was put to serious disadvantage, and consequently the output of raw materials for the dye maker was extremely limited. Coupled with this was the great difficulty in securing men sufficiently trained in the chemistry and manufacturing operations. A great many men took up the manufacture of these products who did not possess a practical acquaintance with the intimate workings of the operations, but who by intensive application and pretenses succeeded in overcoming conditions which, under other circumstances, might have proved unsuccessful.

### AN IMPOSING LIST OF INTERMEDIATES AND DYES

The industry of the intermediates as it stands today in this country is remarkable for the variety of its products, which includes an imposing list of derivatives obtained from benzol and its homologues, numbering about 30, while the list of naphthalene derivatives, including a number of the complicated naphthol and

amido-disulphonic acids, is worthy of special mention. Referring to these naphthalene derivatives used as the starting point for the manufacture of a number of dye-stuffs, it should be kept in mind that with very few exceptions the production of each one constitutes a distinct industry made up of a number of operations. For their proper conduct is necessary a body of men of special training, whether chemists, engineers or workmen, and whose labors are not diverted to other manufacturing operations. Their manufacture is an example of highly specialized work. Some of the chemists who undertook this work were even unfamiliar with the methods of analyzing the finished product, some were unacquainted with the appearance of the operations as one succeeded the other, all of these had to be worked out—there were many failures interspersed with a few successes. But gradually as experience was gained better and more concordant results were being secured, so that in time the quality and the output of the items were constantly increasing.

As the number of the intermediates increased, the number of dyestuffs likewise increased, but the dyer and calico printer were constantly insisting upon a wider range and better dyes and these demands consequently stimulated the dye maker, with the result that during the last forty months the number of dyes actually upon the market increased until there are now about 175 separate and distinct coloring matters of coal-tar origin available and this list is being constantly added to. It is unnecessary to record in this article the list of those dyes, but it may serve our purpose to draw attention to the fact that there are many important members of the group of acid dyes; a wide range of dyes belonging to the direct dye color group; developed colors—a small but gradually increasing number belonging to the same group; sulphur colors—the great majority of which find their application to the production of khaki and olive-drab shades for military purposes; chrome colors which produce the so-called fast shades upon wool with the aid of chromium, a notable example of which is the fast chrome blue used almost exclusively for the dyeing of cloth for sailors' uniforms; and a number of basic dyes which have always occupied a prominent position in the art of textile coloring.

### INDIGO AND ALIZARINE NOW PRODUCED HERE

A number of other products should not be overlooked which do not belong to the above mentioned groups. For example, synthetic indigo; there is now in the process of erection at the Marcus Hook Works, a plant of most modern construction from which will be produced at an early date very large quantities of indigo,

the process for which has been actively prosecuted for a long time and has ultimately reached the point of success where the engineers could take hold and proceed with active operation. At the Brooklyn works of the National company there is now being regularly produced alizarine, from which the dyer produces on cotton the well known Turkey Red shade, and from which may also be obtained a number of other coloring matters, broadly included in the so-called group of alizarine dyes, and by this is meant *true alizarine*.

At one time the idea of producing alizarine in this country was regarded as the most remote possibility. This idea was based upon the fact that the essential raw material for the production was anthracene, which had never been isolated from our domestic tars and without which, of course, alizarine could not be made. When it was definitely decided that alizarine would be made in this country, the separation and refining of anthracene was taken up with energy, with the result that a quality of anthracene has been produced equalling in every way that which has been produced over in England or Germany, and the resulting alizarine, according to the testimony of all dyers, compares most favorably with that which was formerly imported. The energy displayed by the National company in the production of alizarine is merely an augury as to what may be expected by dyers and colorists along the lines of other dyes which are equally difficult to produce. Dyers, as well as consumers of colored textiles, have been insistent for some coloring matters that it has not been possible for the American dye makers to produce, at least for the present. The demand has constantly been made for fast dyes and the query has even been made, Is this or that dye equal to, or as fast as, dyes formerly imported from Germany?

#### OUR DYES EQUAL IN QUALITY TO IMPORTED

This brings forcibly to mind the fact which should not be overlooked, that no dye whether of German or of any other origin is absolutely fast. What the American dye maker tries to do is to produce dyes corresponding in type to dyes that were formerly imported. For example, let us select from the group of basic colors methylene blue. There is no question but that methylene blue possesses certain very good qualities and also certain qualities that do not condemn it for some uses, but the American dye maker has succeeded in duplicating identically methylene blue, and we are today producing in this country equal in shade, strength and working qualities the methylene blue that has been obtained from abroad prior to the war.

If we are asked, Are you making methylene blue as good as the Germans? we must emphatically answer in the affirmative. The same remarks apply to chrysoidine, the methyl violets, saffranine and Bismarck brown. If we refer to the group of sulphur colors with the same question asked us, Are you producing sulphur yellows or sulphur blues in this country equal to those formerly imported from Germany? we answer yes. But, if we are asked, Are you producing every one of such colors as those formerly imported? the answer necessarily must be No, for the reason that the industry of the intermediates has not yet kept pace with the demands. One of the most important groups of colors which interests the wool dyer particularly, is the so-called chrome colors above

referred to. From this class of colors alone the dyer is in position to select quite a number that possess the good qualities of extreme fastness, and many members of this same group now being manufactured in the United States are equal in fastness to their corresponding pre-war types. If again the question is asked, Are we manufacturing in this country every member of the chrome color group? we must again answer in the negative and offering again as the reason, that the industry of the intermediates has not yet supplied to the American dye maker every necessary raw material for the production of members of this important group.

#### CHROME COLORS FOR WAR NEEDS

Another reason also plays an important part, and that is military interests. With a war upon our hands and with conservation laying its hands upon wool in the interest of the army and navy, and we are likewise confronted with the fact that the fastest wool color is commandeered for military purposes and the output of the dye manufacturing plant capable of producing such color is almost solely taken over for war purposes. Coupled with this is the fact that to properly apply these chrome colors, chromium in the form of its well known chemical salts is needed, and the supply of chromium in the form of its ores is demonished so far as importations are concerned. Chromium in the form of chrome iron ore comes from widely separated localities, and while some has been mined in the United States the amount has been small in proportion to the consumption.

As used by the dyer, chromium takes the form of either bichromate of potash or corresponding soda salts. At the moment potash salts are out of the question, while soda salts are produced in limited quantities. The leather industry also requires large quantities of chromium for the chrome tanning process, producing leather for both shoes and harness, besides other military equipment. By far the small amount of chromium which comes to this country in the form of its ores finds its way directly to the steel works, where it plays its part in the war by aiding in the production of chrome steel, largely used for ordnance, projectiles, armor, etc. This disposition of the chrome ore imports is offered as a contributory reason why many chrome colors are now available to the general public

New York City.

**New Method of Preparing Monomethyl Aniline and Dimethylaniline by Catalysis.**—A. Mailhe and F. de Godon.—When a mixture of the vapor of aniline with a slight excess of methyl alcohol is passed over alumina heated at 400 to 430 deg. a mixture of mono and dimethylanilines is obtained which contains only traces of aniline. If methyl alcohol is again added and the process is repeated all the monomethyl derivative is converted into dimethyl aniline. After a certain time the alumina becomes yellow and then brown and its catalytic power is slightly diminished. On calcination it again turns white and recovers its activity. In this new method of preparing the monomethyl derivative the aniline need not be very pure, but may contain water, and the methyl alcohol need not be freed from acetone. The use of autoclaves, compressed air etc. is also avoided, and labor is reduced to a minimum.—*Comptes Rendus*, Vol. CLXVI, March, 1918.

# Direct and Indirect Methods of Nitrogen Fixation\*

Comparison of Operations Involved—Simplicity of the Direct Method—Layout of Battery of Coke Ovens, with Electric Power House and Nitrate Plant

By E. KILBURN SCOTT

I FEEL that the merits of the arc-flame process for making nitric acid have not been adequately and sympathetically considered, and this paper is written with the special object of stating them. I wish also to remove the misconception that the arc-flame process is dependent on water power and that it can only be installed economically on a very large scale. The matter is one of special interest to electrical engineers because the process is essentially an electrical one.

One method of producing nitric acid from air which I call the "indirect" method is first to make carbide of calcium, then treat it with nitrogen to form calcium cyanamide, from which ammonia and in turn nitric acid are obtained.

Another method is the "direct," which consists in combining nitrogen and oxygen of the air directly in the electric arc to form nitric acid.

Those interested in the indirect method have drawn comparisons between it and the direct electric arc process, with the object of showing that the indirect is the better. A tabular comparison of the operations involved in the two processes should thus prove of interest, since it is the only way in which a fair comparison can be made.

It is frequently stated that the amount of electric energy required for a given quantity of nitric acid produced by the indirect process is less than that required by the direct, and this is put forward as a strong argument in favor of the indirect method. The only way to compare two operations is to take into account all the factors which go to make up the total cost, and appraise each one at its proper value.

INDIRECT METHOD, EMPLOYING CALCIUM CYANAMIDE TO MAKE AMMONIA AND OXIDIZING THE AMMONIA TO ACID BY A CATALYST

DIRECT METHOD, EMPLOYING THE ARC FLAME FURNACE ONLY

## FACTORIES

- |                             |                         |
|-----------------------------|-------------------------|
| 1. To make calcium carbide. | 1. To make nitric acid. |
| 2. To make cyanamide.       |                         |
| 3. To make nitric acid.     |                         |

## OPERATIONS

## COMPARISON OF COST OF PLANTS AND OPERATIONS

Obviously, the cost of a plant using the indirect method, will be very much greater than that using the direct, for if we assume that the cost of a carbide furnace and its accessories is about the same as that of an air nitrate furnace with its accessories, then the indirect process embraces in addition:

\*Abstract of a paper presented at the 34th Annual Convention of the A. I. E. E., Atlantic City, N. J., June 27, 1918.

1. A complete plant for making cyanamide.
2. A liquid-air plant for making pure nitrogen.
3. Powerful machinery for grinding the carbide and the cyanamide.
4. Steam boilers and autoclaves for making ammonia.
5. A complete catalytic plant for oxidizing the ammonia to nitric acid.

In the indirect method it is essential to have all the materials, gases etc. absolutely pure: for example at the cyanamide works at Odda in Norway it was necessary to carry a pipe up the mountain side so as to insure a supply of pure air to the liquid-air plant.

When carbide is converted into cyanamide some of the former remains unchanged and in order to obviate danger of explosion a special treatment of the mixture is necessary to insure a total decomposition of the remaining carbide.

Platinum is usually employed and in order to "reactivate" it, it is necessary to subject it to an acid treatment and eventually to remelt, in which process it is impossible to avoid loss of this expensive metal.

By the direct method the cost of air is nil, and the cost of water is practically that of pumping. On the other hand, the materials required in the indirect method are very expensive and especially difficult to obtain at the present time. Over three-fourths of the cost of working the indirect process is represented in materials liable to price fluctuation. These are now much higher than before the war, and will remain at the higher level after the war.

In the direct method less than one-fifth of the total cost is represented in materials dependent on market rates, and the principal item of cost, namely, electric power, will, if anything, tend to come down in price.

The direct method is very simple to operate, while the indirect requires much skilled and unskilled labor, and some of the operations are dangerous to health. Therefore, the more labor demands increase, the more the indirect method will be handicapped in this respect. There are many separate links involving exact operating to make the whole run smoothly; the slightest hitch in connection with any one link necessarily holds up the whole system.

The manufacture of cyanamide has to be carried out in retorts of relatively small size involving much labor to set up etc. This is to enable the nitrogen gas to penetrate to all parts of the contained carbide. The times of the reaction and the cooling down etc. are definitely fixed and it is quite impossible to work the process with off-peak power; moreover, should there be an accident or failure of current for a time, there is every chance of ruining both the cyanamide retorts and the carbide furnaces.

All nitrate processes have a military bearing as regards preparedness, in which is involved the question of transportation. The heavy and bulky raw materials necessary for the indirect process place it at a serious disadvantage from this point of view, especially at the present time when the railways are so congested; with the direct process there is no carriage of raw materials.

As a basic load for a power house the direct arc process presents the advantage that it can be established anywhere, because, the raw materials being only

air and water, considerations of transportation do not enter into the situation.

It is particularly suitable for off-peak or off-season loads, for there is no fused material to solidify and little to deteriorate in case of stoppage. Some of the furnaces can be switched on and off like an arc lamp without detriment to brickwork or structural details, or to the process of manufacture.

As there seems to be some doubt as to the possibility of running arc furnaces intermittently on a commercial scale, I would mention that about seven years ago a nitric acid factory was built at Legnano, Italy, to utilize 10,000 horsepower, especially during the night (see "Utilization of Atmospheric Nitrogen" by T. H. Norton, p. 68). Of course this plant has been considerably extended, especially since the war. I am also credibly informed that in Germany there is a very large arc-process plant working with off-peak power. At any rate there is no difficulty in doing it, whereas it is impossible to work intermittently with any other method of fixing atmospheric nitrogen.

In some ways, it is an advantage to run a plant for 8000 hours per year or less instead of the full number, because the spare time can be conveniently used for renewals and repairs. Less spare time is thus required and the plant can be operated by two shifts of men.

#### SMALL PLANTS PROFITABLE

Because the plants in Norway are very large and use only hydro-electric power, a myth has spread that the arc-flame process can be worked commercially only on a very large scale, and then only with water power. As a matter of fact, it is well worth while to build plants of 10,000-kw. consumption.

Indeed, hydro-electric power may be a disadvantage because of its distance from industrial centers, for either the factory has to be placed in an out-of-the-way location, or else the power has to be carried over a long transmission line. I am of the opinion that electro-chemical factories should be placed near the power supply, and the ideal position is alongside the power house, especially if off-peak power is used.

In a national emergency it is surely better to bring into immediate use all the surplus equipment that already exists than to start building new power houses, whether hydraulic or steam, and inasmuch as the direct-arc-flame process is suitable for working with off-peak power, I would suggest that a number of nitrate plants be forthwith erected at existing power houses.

By erecting ten or more nitrate plants of 10,000 kw. each at power houses near places where nitrates are required, there would be considerable saving in transportation; early deliveries of nitrate could be made. Furthermore, there would be less risk of temporary interruption of supplies in case of accident or sabotage.

There are power houses which could easily spare more than 10,000 kw. for over 20 hours a day and over the week end. Moreover, there are power houses fully equipped with steam plants which are now standing idle. In the present crisis they might just as well be brought into use even if the cost of generation is high.

In some power houses the load factor might be doubled; this would have the immediate effect of reducing costs. But there has been far too much shilly-

shallowly consideration given to questions of cost. With U-boats on the high seas trying to stop supplies of Chile nitrate, the railways congested with traffic and electrical engineering works making munitions, what is the use of discussing power costs?

### COKE-OVEN AND NITRATE PLANTS

At the present time ammonium nitrate is required in very large quantities for burster charges for shells, torpedoes, mines, grenades etc. This is made from two components, viz., nitric acid and ammonia, both of which are difficult to transport, the first because it is a corrosive acid and the second because to every ton of aqua ammonia there are about 2½ tons of water. An industrial process capable of furnishing electric energy as well as a supply of ammonia would be ideal, and it so happens that this is the case with a regenerative coke-oven plant. Half the total gas made is available and this can be easily turned into electric energy while at the same time the nitrogen contained in the coal provides about the right amount of ammonia necessary to combine with the nitric acid made from the electric energy by the arc-flame process.

In order to show how ideal such a system is for making ammonium nitrate, I have prepared the diagram, Fig. 1.

The scheme provides for a combination of a battery of coke ovens with an ammonia-recovery plant together with an electric power house in order to utilize

as shown in the diagram for the purpose of making caustic alkali from brine.

It will thus be seen that the complete project requires only two raw materials, viz., coal and brine, and on the other hand, the products which can be made are coke and ammonium nitrate, together with toluol, benzol, naphtha, tar and sodium nitrate-nitrite.

If electrolytic cells are used, there are also the products chlorine and bleaching powder. The chlorine can be combined with the benzol to form chlor-benzol which is an important intermediate in the manufacture of dyestuffs as well as in the manufacture of picric acid.

From the point of view of efficient management and elimination of transportation charges, the combination is unique, for the ammonia has to be piped only a few yards to the nitrate house and there is no carriage of acid.

As a cheap supply of coal is indispensable for the project, it would be well to locate the plants at industrial centers where this raw material is readily available and where in all probability transportation charges would be low.

### YIELD OF A 100-OVEN BY-PRODUCT PLANT

In order to show what can be done with a coke-oven plant the following particulars will be of interest. I take a Koppers type of oven as being the best known.

| Quality of Coal                                                             | Tons per charge | Hours coking time |
|-----------------------------------------------------------------------------|-----------------|-------------------|
| Low-volatile coal                                                           | 13½             | 18                |
| Mixture containing 80 per cent high-volatile, 20 per cent low-volatile coal | 12½             | 16½               |
| High-volatile coal                                                          | 11½             | 15                |

A battery of ovens varies in size but we may as well take a round number of 100, for which the average yields are as follows:

|                                          |        |
|------------------------------------------|--------|
| Number of ovens                          | 100    |
| Tons of coal per oven                    | 12½    |
| Hours coking time                        | 16     |
| Total yield of coke, per cent.           | 72     |
| Yield small coal and breeze, per cent.   | 5      |
| Net yield good coke, per cent.           | 67     |
| Ammonium sulphate per ton of coal, lb.   | 25     |
| Reckoned as ammonia per ton of coal, lb. | 6½     |
| Tar per ton of coal, gal.                | 9      |
| Light oil per ton of coal, gal.          | 3      |
| Total gas per ton of coal, cu.ft.        | 11,000 |
| British thermal units, per cu.ft.        | 550    |
| Surplus gas, per cent.                   | 55     |
| Surplus gas per ton of coal, cu.ft.      | 6,000  |

Such a battery of ovens, each of which distills 12½ tons of coal in 16 hours, will deal with

$$100 \times 12.5 \times 24 = 1900 \text{ tons per day.}$$

Assuming 6000 cu.ft. of surplus gas per ton of coal and 550 B.t.u. per cu.ft., the total heat value per hour will be

$$\frac{1900 \times 6000 \times 550}{24} = 260,000,000 \text{ B.t.u.}$$

If employed in gas engines using 13,000 B.t.u. per hp.-hr., the power will be

$$\frac{260,000,000}{13,000} = 20,000 \text{ hp., or about 14,000 kw.}$$

If steam boilers and turbines are used instead of gas engines, the power will be less; so to be on the

FIG. 1. SYSTEM FOR MAKING AMMONIUM NITRATE

the surplus gas. Alongside of the power house, there is an electrochemical plant for the manufacture of nitric acid from air by utilizing the three-phase high-tension current. A nitrate house is provided for the purpose of combining the ammonia from the coke ovens with the nitric acid from the electrochemical plant.

It happens that the by-product of the acid factory is sodium nitrate-nitrite, which is made by combining the gases remaining from the acid towers with caustic soda or soda ash. Electrolytic cells may be laid down

safe side, we will take the round figure of 10,000 kw.

We will also assume that electric furnaces utilizing 10,000 kw. for a whole year can produce 6300 tons of 100 per cent nitric acid capable of furnishing theoretically 8000 tons of ammonium nitrate, as indicated:

|                        |                                                       |      |      |
|------------------------|-------------------------------------------------------|------|------|
|                        | $\text{NH}_3 + \text{HNO}_3 = \text{NH}_4\text{NO}_3$ |      |      |
| Molecular weights..... | 17                                                    | 63   | 80   |
| In short tons.....     | 1700                                                  | 6300 | 8000 |

Allowing 25 lb. of sulphate of ammonia or  $6\frac{1}{2}$  lb. of ammonia per ton of coal, a total consumption of 1900 tons of coal per day should give

$$1900 \times 365 \div 6.5 = 2250 \text{ tons per annum.}$$

It will thus be seen that there is plenty of ammonia to combine with the acid made by the surplus gas, even if a higher yield of acid is allowed per kw.-yr. and more power is generated.

I purposely leave out of consideration questions as to types of nitrogen fixation furnaces and of yields obtained. I may say, however, that it is not right to assume that yields are limited to those usually obtained from certain well-known furnaces which must of necessity work with single-phase current.

The amount of ammonium nitrate will be less than the theoretical figure because the efficiency of the reaction is not 100 per cent; moreover, it is usual to convert a certain amount of the gas into sodium nitrate-nitrite. A safe figure would be 6000 tons and at this rate it can be shown that with electric energy at 5 mils per kw.-hr. and ammonia at 13c. a pound, the ammonium nitrate can be made at less than half the price the government is now paying.

#### MAGNITUDE OF THE NITROGEN INDUSTRY

In order to show how large a business the nitrogen industry has become, the following figures (compiled by Dr. Paul J. Fox) give the nitrogen balance sheet for the United States for 1917.

##### IMPORTED SUPPLIES

|                                                                              | Tons of 2,000 lb. | Tons of Nitrogen |
|------------------------------------------------------------------------------|-------------------|------------------|
| Chile saltpetre, 95 per cent $\text{NaNO}_3$ .....                           | 1,742,540         | 272,880          |
| Ordinary saltpetre, potassium nitrate.....                                   | 4,609             | 645              |
| Ordinary saltpetre and gunpowder containing 75 per cent $\text{KNO}_3$ ..... | 1,500             | 210              |
| Ammonium sulphate.....                                                       | 8,135             | 1,720            |
| Ammonium chloride.....                                                       | 1,073             |                  |

##### DOMESTIC SUPPLIES

|                                                |         |        |
|------------------------------------------------|---------|--------|
| Coke oven ammonia— $\text{NH}_3$ .....         | 113,760 | 93,625 |
| Gas works ammonia— $\text{NH}_3$ .....         | 12,500  | 10,288 |
| Calcium cyanamide at 20 per cent nitrogen..... | 12,800  | 10,534 |

##### NITROGEN EXPORTED

|                                                           |         |        |
|-----------------------------------------------------------|---------|--------|
| Nitric acid, 15 per cent nitrogen.....                    | 486     | 73     |
| Picric acid, 18 per cent nitrogen.....                    | 26,610  | 4,790  |
| Dynamite, 12 per cent nitrogen.....                       | 8,962   | 1,255  |
| Gunpowder and smokeless powder, 13 per cent nitrogen..... | 223,270 | 29,025 |
| Ordinary saltpetre.....                                   | 875     | 123    |

In addition to the above, there is also about 8800 tons represented as nitrogen in the following items which are the figures for 1917.

|                             | Value         |
|-----------------------------|---------------|
| Loaded cartridges.....      | \$42,000,000  |
| Fuses.....                  | 34,000,000    |
| Shells and projectiles..... | 74,000,000    |
| All other.....              | 202,000,000   |
| Total.....                  | \$253,000,000 |

It will be noticed that ammonium nitrate is not included in these figures, but I assume it would be about 50,000 tons for 1917.

In Great Britain the consumption of ammonium nitrate is now probably 400,000 tons a year, and the

production here will have to be at least as much. To make this, the theoretical proportion of ammonia required is about 85,000 tons and of nitric acid about 315,000 tons.

It will thus be seen that the coke-oven plants in the country could supply all the ammonium nitrate required if they were put on the job.

#### GENERAL CONSIDERATIONS

Until recently most coke-oven ammonia was converted into sulphate, but owing to the war demand for nitrate, more and more of it is being made into aqua ammonia of about 29 per cent strength. In some cases this is being transported many hundreds of miles prior to conversion into ammonium nitrate and since each ton of ammonia necessitates the transportation of about  $2\frac{1}{2}$  tons of water, the bearing of this on the present railway congestion is at once apparent. Tank cars have to be used and they must return empty, so the freight on the actual ammonia carried is extremely high.

There are many coke ovens of the wasteful bee-hive type in operation, which do not recover by-products. The replacement of these by modern coke-ovens would be a great immediate economic gain and meet the war conditions better than the building of large dams for water power.

In the present emergency coke ovens are of great value because they give coke for making steel, gas for power purposes, ammonia for nitrate manufacture, and toluol and benzol for explosives.

After the war ammonium nitrate will be in demand for fertilizer as well as for safety explosives and other purposes. The high percentage of nitrogen which it contains, 35 per cent, and the ease with which it can be converted into other compounds makes it especially useful for conveying nitrogen in the fixed form over considerable distances.

It is more profitable to make nitrate than sulphate, because pound for pound, the nitrate contains nearly twice as much fixed nitrogen and the nitrogen commands a higher price per unit when in the form of ammonium nitrate.

New York City.

#### Jellies Formed by Dyes

When certain substantive dyes, Benzopurpurin B and Chrysophenin B, are dissolved in hot water, solutions are obtained which jelly on cooling. The formation of the jellies seems to be dependent on small quantities of electrolyte in the dyes, for when the solutions are purified by dialysis, coagulation takes place and the coagulum is no longer soluble even in hot water. The addition of sodium chloride is, however, sufficient to bring the dye into solution. The experiments show that the small quantities of electrolytes (sulphates and chlorides) present in the commercial substantive dyes are very important in technical application, but as yet no satisfactory explanation of the phenomenon can be given.—*Kolloid Zeits.*

The volume of natural gas from which the output of natural-gas gasoline in 1917 was recovered is estimated to have amounted to about 429,000,000,000 cu.ft., and the average recovery of gasoline per thousand cubic feet was about one-half gallon.

# The Distillation of Coal in a Vacuum\*

## Nature of Products Obtained and Their Relation to Ordinary Tar and Petroleum in Chemical Constitution

By AMÉ PICTET

Professor of Chemistry, University of Geneva

WHEN we consider the part that coal plays in belief that this precious material had long been the modern world, we would be inclined to the subject of thorough and definitely scientific study, and that its chemical nature particularly was no longer a secret. As a matter of fact, this is not true. The chemistry of coal still presents considerable blanks. If we know accurately its elementary composition and the calorific power of all the varieties, if we know exactly all the products which it yields upon heating, we are still ignorant of what it is in its natural state and of what organic bodies it is composed.

This knowledge would be very important to science and industry, for it would render possible the solution of a number of important questions which are still unsolved and which have a bearing upon, among others, the genesis of fossil coals and their relation to petroleum and bitumens, upon the slow transformations to which they are subjected in the earth and to those more rapid transformations which they undergo during cokefaction, etc.

The ignorance in which we are left in this domain, however, must not be imputed to the indifference of the chemists; it is attributable only to the insufficiency of the means at their disposal. To separate the constituents of an intimate mixture, they have in effect but two processes: Fractional distillation and the action of solvents. Now, neither the one nor the other is practicable in this particular case, for coal is not volatile without decomposition and does not dissolve easily in any known liquid.

In spite of these inherent difficulties of the subject, I have thought that the latter deserved to be undertaken and that it would be possible to overcome some one of the obstacles by changing suitably the operating methods used up to the present time. Several years ago with the assistance of several co-workers, MM. L. Ramseyer, M. Bouvier, O. Kaiser and A. Labouchère, I entered upon some original research upon the chemical nature of coal. These studies are far from being finished; their first results have led however to some conclusions which may perhaps be interesting.<sup>1</sup>

### METHOD OF RESEARCH

We have been guided in our first experiences by the following considerations. When coal is distilled at atmospheric pressure as is practiced in gas works and in coke-plants, it is necessary, in order to extract all the volatile properties, to heat it to a very high temperature (800 or 1000 deg.). It is evident, that under these

conditions, the products that are collected, and which form the illuminating gas, the ammoniacal water and the tar, must be considered as pre-existent in the coal, and not as resulting from its immediate decomposition. They have undergone, due to the high temperature to which they have been brought, various transformations, the nature of which has escaped us. We cannot deduce from their chemical constitution any index as to the more complex compounds from which they have been derived.

There is only one way to avoid these transformations and that is to conduct the distillation at a much lower temperature and at a very reduced pressure. Acting upon this principle, we have subjected to vacuum distillation several kilos of a fat coal coming from Mont-rambert (Loire). The simple apparatus which we used has been described elsewhere, and I shall not repeat it. We have found that at a pressure of 15 mm. of mercury, distillation begins at about 100 deg. and that it is entirely terminated at 450 deg., that is to say, a little above the point where it would begin if operated under ordinary pressure.

### NATURE OF PRODUCTS OBTAINED

The products obtained are of an entirely different nature and are as follows:

1. *Gases.* The apparatus which we adopted did not permit us either to measure them or determine their composition; we have only been able to observe that their odor is much different from that of illuminating gas and resembles that of butadienes and isoprenes.

2. *Water.* About 1.6 per cent of the weight of the coal presented an acid reaction and did not contain ammonia.

3. *Tar.* About 4 per cent; very different from ordinary tar in appearance and all its properties.

4. The *coke*, lighter, more friable and more easily combustible than ordinary coke, resembled rather that which remains after the distillation of petroleum.

Of these products, the tar seemed to be the most interesting, and we studied it first. To procure a sufficient quantity, we applied to the Society of Chemical Industry at Bâle which was so kind as to distill in a vacuum for our purpose one and one-half tons of the same Montrambert coal, which yielded us about 60 kilos of tar.

### THE VACUUM TAR

The vacuum tar, as we have called it, is a translucent liquid, light brown and has a light green fluorescence; it is more fluid than ordinary tar and has an odor very different, resembling that of petrol. Immediately after its preparation it floats upon the water which it has entrained but it soon thickens, sinks and increases in

\*Translation from *Revue Generale des Sciences*, Oct., 1916, Vol. 27, pp. 578-584.

<sup>1</sup>For experimental details, see *Comptes Rendus*, vol. CLVII, pp. 779 and 1436; vol. CLX, p. 629, as well as the theses of M. Ramseyer (Geneva, 1911) and M. Bouvier (Geneva, 1915).

density. At the end of three days, the density is exactly equal to 1; it rises again eventually. This phenomenon takes place when the air is excluded as well as in the presence of air; it is not, therefore, due to oxidation.

In connection with this fact, it was observed that the tar agitated soon after its preparation with an excess of solution of caustic soda does not give up anything. Therefore it does not contain phenols, but the latter appear after a certain time and their quantity increases quite rapidly.

Treated with dilute hydrochloric acid, the vacuum tar yields a small quantity (about 0.5 per cent) of compounds of a basic nature. Their study has been undertaken by M. Labouchère. Some of these substances are secondary bases, and others tertiary. These belong chiefly to the hydropyridic and hydroquinoline series. The only two of which have been isolated thus far in their pure state have the formulae,  $C_{10}H_{11}N$  and  $C_{12}H_{13}N$  and very probably constitute dihydromethylquinoline and dihydro-trimethylquinoline.

After this double treatment by soda and by hydrochloric acid, the vacuum tar still contains some oxygen compounds (about 2 per cent). These can be obtained by boiling the liquid with sodium. The compounds have some of the properties of the alcohols. MM. Bouvier and Kaiser have been able to isolate by fractional distillation four well-defined representatives of this class of bodies. They answer to the formulas,  $C_7H_{11}O$ ,  $C_8H_{14}O$ ,  $C_9H_{17}O$  and  $C_{10}H_{20}O$ .

The first of these alcohols is saturated and constitutes the p-methyl-cyclohexanol (hexahydro-paracresol). The other three which form a homologous series belong to a group of unsaturated alcohols. Their structure has not yet been established; we have only ascertained that they are but slightly stable. Completely insoluble at first in alkalis, they become part soluble after a short time; the solution is disturbed when a current of carbonic gas is passed through it, and one can distinguish bodies having the odor and all the properties of phenols. This transformation which is probably isomerisation, furnishes the key to the phenomenon which has been a baffling question.

Once rid of bases and alcohols, the vacuum tar is nothing more than a mixture of hydrocarbons, of which some are saturated and others are not. To separate them we have made use of the Edelineau process, which has been employed for several years in the refining of petroleum. It consists in agitating the mixture, suitably refrigerated, with twice its volume of liquid sulphurous anhydride. Only the unsaturated hydrocarbons pass into solution and can be recovered simply by volatilization from the solvent. The saturated hydrocarbons serve to float the sulphurous solution and are separated mechanically. This process, applied to vacuum tar, has given us excellent results and has permitted us to separate our product very nicely into two parts, the one, unsaturated, the other saturated, the first having a volume about double that of the second.

We afterward subjected these two parts to a series of fractional distillations two degrees apart. The two parts behaved almost the same. The distillation began at 120 deg. and ended at 350 deg. There remains a small quantity of a black material of the consistency of asphalt.

All these fractions up to 300 deg. remain liquid after cooling. None of them deposits crystals. This indicates that no noticeable quantities of naphthalene, anthracene or other aromatic solid hydrocarbons are found. We have oxidized many of them by means of potassium permanganate and have found but few acids of the fatty series (acetic, propionic, butyric, oxalic). It seems very certain that vacuum tar contains no phenols nor any more hydrocarbons of the aromatic series.

We have studied the lower fractions especially. They are liquids, insoluble in water and volatile with it. They have the odor of petroleum and are inactive to polarized light. M. Bouvier has determined their composition, their molecular weight, their density and their refraction indices and has succeeded in determining the constitution of some by converting them into known bromine and nitrogen derivatives. These observations establish the presence of the following compounds in vacuum tar:

*Saturated Hydrocarbons.* These all have the same centesimal composition corresponding to the general formula  $C_nH_{2n}$ ; they are therefore cyclanes:

$C_6H_{12}$ , boiling point 135-137 deg. (hexahydro-mesitylene)

$C_{10}H_{20}$ , boiling point 172-174 deg. (hexahydro-durene)

$C_{14}H_{28}$ , boiling point 189-191 deg.

$C_{18}H_{36}$ , boiling point 211-213 deg.

$C_{22}H_{44}$ , boiling point 227-229 deg.

$C_{26}H_{52}$ , boiling point 218 deg. at a pressure of 0.5 mm.

The last hydrocarbon is solid at ordinary temperature and is deposited with the last fraction (above 300 deg.). It crystallizes in acetone in pearly scales, melting at 62-63 deg. We have found it identical with melene which Brodie separated in 1849 from the products of dry distillation of beeswax.

*Unsaturated Hydrocarbons.* These have been isolated to date in a pure state, as dihydro-trimethylbenzene,  $C_{10}H_{16}$ , boiling at 163-164 deg., and a hexahydrofluorene,  $C_{14}H_{20}$ , boiling at 240-250 deg., and it is very probable besides that the lower fractions contain dihydrogenous derivatives of metaxylene, of mesitylene and of pseudocumene for they yielded these hydrocarbons by careful oxidation.

#### RELATION OF VACUUM TAR TO ORDINARY TAR

It is recognized that all the constituents of vacuum tar, whose nature we have been able to determine, belong to the hydro-aromatic series. The aromatic compounds of ordinary tar are replaced in our product by their hydrides. The homologs of benzene make place for those of cyclohexane and cyclohexadienes, the phenols for the alcohol, the quinoleique bases to their dihydrogenic derivatives.

It is seen that these hydrides when they are carried to a high temperature, have a tendency to lose a part of their hydrogen, to be converted into more stable aromatic compounds. It was then assumed that a phenomenon of this kind takes place in the gas retorts and that the hydrides of vacuum tar first form here and undergo with a higher temperature an immediate pyrogenous dehydrogenation. Vacuum tar would represent then an intermediate stage in ordinary tar formation.

This supposition was easy to verify by test. We took 200 g. of vacuum tar in its raw state, that is to say, not yet separated from its alcohols and bases, and caused it to run drop by drop into a red-hot iron tube,

first filled with pieces of coke (in order to realize as much as possible the conditions of the gas retort). At the other end of the tube we collected:

1—Gases (20-30 liters). These had the odor of illuminating gas and burned with a brilliant flame; they are composed of hydrogen and methane, accompanied by a little ethylene, but no acetylene.

2—Water strongly charged with ammonia.

3—A tar having the appearance and the odor of ordinary tar and from which we were able to separate benzene, toluene, xylenes, phenols, a small amount of naphthaline, anthracene and pyridic bases.

These are the principal constituents of ordinary tar. Their absence having been duly proved in the vacuum tar, the hypothesis which we have announced seems to us to be justified; the hydrogen and the methane of illuminating gas, the ammoniacal water of illuminating gas, the phenols and the aromatic hydrocarbons of tar, are not at all the immediate products of the dry distillation of coal. They are only formed at high temperatures by the decomposition of other more complex volatile compounds, and in particular the more hydrogenated ones which are formed at a lower temperature.

#### CONTRADICTION OF BERTHELOT'S THEORY OF COAL TAR

This interpretation is in contradiction with the theory of Berthelot on the formation of coal tar. It is known that the latter theory consists in admitting that upon distillation the coal is decomposed entirely into very simple products—carbon, hydrogen, water vapor, ammonia, methane, ethylene, acetylene. On contact with the cold walls of the retorts, the last of these gases, notably acetylene, undergoes a series of polymerizations and condensations which give rise to diverse aromatic hydrocarbons of tar. This is also a product of synthesis.

Berthelot has based this theory, not only on a direct study of the decomposition of coal, but on experiments of pyrogenation to which he has submitted the acetylene itself. These experiments which have been repeated recently on larger scale, but with an identical result, by M. R. Meyer at Brunswick, have established the fact that the acetylene is polymerized to a dark red and yields benzene, and that the two hydrocarbons then unite in turn to produce naphthaline and that finally it is possible to obtain by means of pyrogenated condensation of the same kind almost all of the hydrogen carbides which are found in tar.

However interesting these syntheses may be, should it necessarily be deduced that they are brought about in the gas retorts? One can only assume this, it seems to me, when it has been proved that the coal upon heating liberates great quantities of acetylene. Now this proof has not, to my belief, yet been established.

This argument would not constitute however serious objection to the theory of Berthelot even if it had been corroborated by some recent experimental facts. Perhaps it will be accepted that our study of vacuum tar supports some of these facts, and that the new explanation which I propose merits substitution in a large measure what has held up to the present time.

I say in a large measure, for my interpretation, it seems to me, ought to be applied to the major part of the reactions which take place during the distillation of coal, since this yields almost the same quantity (4 per cent) of vacuum tar as ordinary tar. However, I

realize that this does not yet account for all of these reactions. Moreover, we have not been able to discover in our tar any of the hydrogen derivatives of naphthaline. This hydrocarbon, if it exists in ordinary tar, must then have a different origin than the others, and it is highly probable that it originated through a synthetic process similar to that which Berthelot admitted. The following observation seems justified in clearing up this point. We have found that a very considerable quantity of naphthaline was formed when the vapors of cyclohexane are conducted over coke heated to redness (the vapors of benzene under these conditions yield only biphenyls). Since the cyclohexane reappears in the series of the saturated hydrocarbons which we have derived from vacuum tar, there can be seen in this reaction the source from which the naphthaline of ordinary tar proceeds.

#### RELATIONS OF VACUUM TAR TO PETROLEUM

Allusion has been made in the preceding pages to analogies that vacuum tar present to petroleum. These analogies have been noticeable not only in the physical properties of the two liquids, but also in their chemical composition. After having isolated the series of cyclanes mentioned above, M. Bouvier and I compared their properties with those naphthenes which form the essential part of certain petroleum. This comparison has shown us that the naphthenes of Baku petroleum are not identical with the cyclanes of vacuum tar. For an identical formula, they have a higher density and a higher boiling point. On the other hand, we have found a remarkable similarity between the properties of our hydrocarbons and those which M. Mabery<sup>7</sup> attributes to the naphthenes which he has derived from certain petroleum from North America (Canada and California). Table I shows the results of his investigation.

TABLE I.—RELATION OF VACUUM TAR TO PETROLEUM

| Vacuum Tar    |                                 |         |                     | American Petroleum |                                 |         |                            |
|---------------|---------------------------------|---------|---------------------|--------------------|---------------------------------|---------|----------------------------|
| Fraction Deg. | Formula                         | Density | Index of Refraction | Fraction Deg.      | Formula                         | Density | Index of Refraction Source |
| 135-137       | C <sub>9</sub> H <sub>18</sub>  | 0.7590  | 1.4212              | 135                | C <sub>9</sub> H <sub>18</sub>  | 0.7591  | Cal.                       |
| 172-174       | C <sub>10</sub> H <sub>20</sub> | 0.7765  | 1.4196              | 173-174            | C <sub>10</sub> H <sub>20</sub> | 0.7770  | 1,4149 Can.                |
| 189-191       | C <sub>11</sub> H <sub>22</sub> | 0.7838  | 1.4234              | 189-191            | C <sub>11</sub> H <sub>22</sub> | 0.7832  | 1,4231 Can.                |
| 211-213       | C <sub>12</sub> H <sub>24</sub> | 0.7862  | 1.4293              | 212-214            | C <sub>12</sub> H <sub>24</sub> | 0.7857  | 1,4289 Can.                |
| 229-237       | C <sub>13</sub> H <sub>26</sub> | 0.7953  | 1.4379              | 228-230            | C <sub>13</sub> H <sub>26</sub> | 0.7979  | 1,444 Can.                 |

It cannot be doubted in considering the results set forth in this table but that there has been found here unmistakably these identical hydrocarbons. I might add that we have separated from the last fractions of distillation of Galician petroleum a solid hydrocarbon of the formula C<sub>10</sub>H<sub>20</sub> which was shown to be identical in all its properties with the melene of vacuum tar.

We determined also the unexpected fact that we could separate from coal, by simple distillation, a series of compounds which constitute an integral part of certain petroleum. It is the first time, we believe, that there has been found a relation of a chemical nature between these two natural combustibles.

#### RELATION OF VACUUM TAR TO COAL

One point remains to be cleared up: Do the various compounds which form vacuum tar exist as such in the coal, or are they produced during the process of distillation?

<sup>7</sup>Journal of the American Chemical Society, Vol. XIX, p. 470; Vol. XXV, pp. 267 and 276; Vol. XXXIII, p. 261.

To be able to answer this question, it is necessary to revert to the methods of exhausting coal by appropriate liquids. Considerable work has already been done on this subject. Since the time of Comines de Marcilly (1862), it has been pursued almost without interruption down to the present time. Investigators have been especially concerned, however, with establishing the relative power of extraction of various solvents, and their authors have not succeeded up to the present in separating from the extracts any definite bodies of which they have been able to determine the structure or even the composition.

I have undertaken these experiments with MM. Ramseyer and Kaiser. As a solvent, we chose benzol. We then worked with small quantities of this same Mont Rambert coal, which was used in our experiments with vacuum distillation. Later, thanks to the valuable assistance rendered us by the house of F. Hoffman, La Roche and Company at Bâle, the same operation was repeated on a larger scale (with  $5\frac{1}{2}$  tons of coal); at that time, however, a Sarre coal (Maybach) was used in the work.

#### BOILING BENZOL AS A SOLVENT

In the two cases the coal, crushed in pieces the size of a pea, was treated with boiling benzol for four days in the apparatus of the Soxhlet system. The solution was immediately reduced to a strong concentrate and to it was added five times its volume of petroleum ether (boiling point 35-90 deg.). It precipitated a clear brown amorphous powder, which we have not yet studied. The solvent was then driven off by heating to 100 deg. There remained a pale brown liquid, somewhat fluid, possessing an odor of petroleum and a density exactly equivalent to 1.000 at 20 deg.

The five tons treated at Bâle yielded 2.7 kilograms of solid substance and 10.6 kilograms of liquid extractive. The yield was then 0.25 per cent.

The liquid extract obtained from the Montrambert coal was especially studied from the point of view of the less volatile substances which it might contain. Without entering into more of the details of this part of our study, I will simply say that we are able to separate the same hexahydrofluorene  $C_{12}H_{18}$  and the same melene  $C_{12}H_8$  as was found in the vacuum tar.

As to the liquid extract of the Sarre coal a large quantity of which we had on hand, we decided, on the other hand, to study its more volatile products. This extract possessed not only the odor and density of vacuum tar but also a very similar composition. It was formed, like it and in similar proportions, of saturated and unsaturated hydrocarbons and about 2 per cent alcohols and bases. In separating these bodies we proceeded in exactly the same manner as we had formerly, that is to say, by successive treatments with hydrochloric acid, sodium, liquid sulphurous anhydrides, then fractional distillation.

The definite hydrocarbons which we have isolated up to the present are given in Table II. M. Kaiser was able to determine the structure of the first three by converting them into known nitrogen and bromine compounds, and was able to establish the identity between the last three compounds and the cyclanes of the same formulas separated from the vacuum tar and the petroleum of Canada.

It is evident then that there can be extracted from the coal by means of boiling benzol (80 deg.) a series of hydrocarbons which are identical or very analogous to those yielded by vacuum distillation. This last operation then only separates them by simple volatilization, and we are safe in concluding that a part at least of the components of vacuum tar exist already formed in the coal.

They occur then as a solid hydrocarbon substance impregnated with a liquid chemically akin to petroleum. That this liquid has been formed through a slow decomposition of the solid mass, is the probable explanation, when we consider the formation of fire-damp which has been proved in all coal deposits, as well as the existence of the natural gas sources which are sometimes located in the proximity of these deposits. Fire-damp and natural gas are mixtures of hydrocarbons.

TABLE II.

| Unsaturated Hydrocarbons |               |                       |
|--------------------------|---------------|-----------------------|
| $C_7H_{10}$              | boiling point | 108-110 deg.          |
| $C_8H_{12}$              | boiling point | 135-137 deg.          |
| $C_9H_{14}$              | boiling point | 166-168 deg.          |
| $C_{10}H_{16}$           | boiling point | 180-182 deg.          |
| $C_{11}H_{18}$           | boiling point | 200-202 deg.          |
| $C_{12}H_{20}$           | boiling point | 236-238 deg.          |
| $C_{13}H_{22}$           | boiling point | 251-254 deg.          |
| $C_{14}H_{24}$           | boiling point | 251-254 deg.          |
| $C_{15}H_{26}$           | boiling point | 251-254 deg.          |
| Saturated Hydrocarbons   |               |                       |
| $C_8H_{18}(?)$           | boiling point | 118-122 deg.          |
| $C_9H_{20}(?)$           | boiling point | 135-138 deg.          |
| $C_{10}H_{22}(?)$        | boiling point | 172-174 deg.          |
| $C_{11}H_{24}$           | boiling point | 190-192 deg.          |
| $C_{12}H_{26}$           | boiling point | 215-216 deg.          |
| $C_{13}H_{28}$           | boiling point | 227-229 deg.          |
|                          |               | Dihydro-toluene       |
|                          |               | Dihydro-metaxylene    |
|                          |               | Dihydro-mesitylene    |
|                          |               | Dihydro-prelnitol (?) |
|                          |               | Dihydro-fluorene (?)  |

The analysis gave us figures a little too high as to hydrogen content, thus indicating the presence in slight amounts of hydrocarbons of  $C_nH_{2n+2}$  formula.

Identical in every respect with the hydrocarbons of the same formula obtained from vacuum tar and petroleum from Canada.

It is possible to conceive that near these gaseous products the spontaneous decomposition of coal could form from them others of the same chemical nature but which at the surrounding temperature are liquid and slightly volatile. They would remain necessarily embedded in the solid mass, from which vacuum distillation or even a simple washing with benzol could separate them.

We could go even farther and couple the origin of actual petroleum deposits to a decomposition of this kind which will come in due time. But this idea meets with numerous objections of a geologic nature. Its discussion in the present state of our knowledge would be premature. I prefer then not to touch upon this point here, and to limit myself to this short resumé of the experimental research which my co-workers and I have done on the coal itself. I believe it to be my duty to refrain for the time being from considering the industrial applications which our methods may receive. They will appear better when our research has become further advanced.

**The Natural Indigo Industry.**—With the cutting-off of the supplies of synthetic indigo from Germany since the outbreak of war, the cultivation of natural indigo has increased considerably. While the total area under this crop in 1914-15 was only 148,400 acres, in 1915-16 it rose to 353,100, and in 1916-17 to 756,400 acres. The greatest increase, both relative and absolute, occurred in the Madras Presidency and in the United Provinces, where the industry is mainly in the hands of small holders, and the dye manufactured is of an inferior quality.

### Increasing Production of American-Made Potash

ACCORDING to the figures given out by the U. S. Geological Survey, the production of potash for the first half of this year was between 20,000 and 25,000 tons of  $K_2O$ , and it is estimated that the total for the year will reach 60,000 tons, as compared with 32,575 tons in 1917. This is about 25 per cent of our pre-war importations, and if this country is to become independent of Germany, immediate steps should be taken to further develop our own sources of supply. The cement works and blast furnaces alone should be able to supply our total requirements, but so far these industries have done very little. By the end of 1918 about a dozen cement companies will be recovering potash as a by-product, and incidentally abating the dust nuisance. The blast furnaces are doing practically nothing although it is generally recognized that they would benefit considerably by obtaining cleaner gas for the stoves and gas engines. The manufacturers can hardly be blamed for not putting money in the necessary additions to their plants under the present uncertainty of the whole potash question. Although the present prices are high, no one knows how long they will last, and under the proposed revenue bill most of the profits would be taken by the government as taxes. The manufacturers would not object to this if they were allowed to amortize the cost of plant before being subject to any profits tax. The producers of potash should also be given definite assurance by the government that there will be no "dumping" of German potash after the war.

A source which it seems to us should be thoroughly investigated is the potash-bearing silicate rocks. There are large deposits of these running fairly high in potash, notably the greensands of New Jersey, the leucite deposits of Wyoming, and the sericites and potash-bearing states of Georgia. Although no commercially successful method of extracting potash from silicate in general has as yet been developed, this problem should not be beyond the skill of American chemists and metallurgists. Congress granted an appropriation of \$175,000 in 1916 to the Department of Agriculture for an experimental plant for treating kelp, and it seems to us that the silicates offer an even more promising source of potash. We think it would be a very good idea if a similar appropriation were made to the Bureau of Mines for carrying out experiments on these silicates, as if a successful process of extracting the potash can be developed, the supply of raw material is practically unlimited.

Our recent editorial comments on the advisability of

searching iron ores and fluxes are ably supported by the article of Mr. Grasty on "Potash as a By-product," published elsewhere in this issue. The author makes a timely point when he avers that our future production of potash must compete with the German product, and that we must consequently rely on cheap sources of supply. By-product sources usually are inexpensive. The cement industry is already doing something in this line, and the blast-furnace must support in larger measure the production of the cement kiln.

### The Evaporation of Weak Liquors.

MANY chemical and metallurgical processes are broken by the cost of evaporating large quantities of weak solutions. Others are more fortunately situated as regards the price of heat or the relative quantity of liquid to be removed. In any case, men who are responsible for the evaporating practice in scores of chemical processes should find much of interest in the article published in this issue on "A Wet Process for Extracting Potash from Cement Dust," in which is described a rather unique condenser-evaporator installation. Briefly, this particular process required the production of a very humid gas, the cooling of this gas approximately to atmospheric temperature, and the collection of its precipitated mist. The practical operation developed a method of conserving furnace energy far beyond the power of the ordinary waste-heat boiler, and apparently applicable to many processes—at least meriting most careful consideration.

Conventional evaporating practice involves the production of large quantities of live steam by the most efficient boiler practice, and the utilization of the latent and sensible heat of the vapor in multiple-effect evaporators. Boiler gases escape at a temperature well above that of the steam produced, and usually carry with them large amounts of heat which go to waste except for the production of draft. Mr. Dean's process takes such gases, reduces them to temperatures but little above the atmosphere, and utilizes the abstracted heat for evaporating purposes. Indeed, it might prove to be more profitable to throw more work on the condenser-evaporator unit, and less on the boiler by eliminating any economizers, which by the way, are often regarded by their possessors as diluted blessings.

### Outlook for German Competition in Potash

AT THE potash symposium yesterday Mr. Linn Bradley sounded a note of warning against the danger of national lethargy in recognizing the importance of potash independence. He also pointed out the certainty of German competition after the war and called for national support of the domestic potash industry. His sentiments coincide with those of others who have given the subject consideration, and we are glad to give them publicity in these columns in view of the importance of the matter.

"It seems ridiculous that the United States should be playing the rôle of food granary for ourselves and our allies, also raising the cotton which is so necessary in connection with the war, and yet nothing is being done to provide the potash either for food purposes or for the

cotton, except the limited and inadequate efforts due to private initiative. It ought to be emphasized that potash is a subject which should be understood and appreciated by everyone in the nation, and that it should be considered primarily from the national point of view. Does any one of us imagine that there is such ignorance of potash in Germany as exists among our own citizens? No, they have learned that potash is the big German raw-material and economic weapon which they counted upon and are still counting on to help the Kaiser impose his will on you and on me.

"To all those who are assisting in the solution of the problem, I would state that we should soon take steps to solve our post-war problems. The question of the market conditions which will prevail is ever before us. Germany will do all within her power after peace is declared to break down that which will have been built up, the same as she has destroyed the beautiful cities of France. She will endeavor to regain control of the potash situation in this country. Even now she probably has her propaganda all prepared and ready for launching. One need not be surprised to learn that she has agents in the various Governmental departments and bureaus in Washington ever ready to interfere with efforts being made by our technical and business men. Even now we hear rumors to the effect that potash is not a plant food and is not needed for cotton, potatoes and various other crops. Careful investigation of the southern cotton fields should be convincing that this may be another piece of German propaganda. It is difficult to check up these rumors, but all of us should be on guard against them.

"It would be to the national interest in the broadest way for this country to take steps to forever exclude every ounce of German potash. Tariff, price control and other methods should be earnestly considered. The farmer must be made to realize that he dare not use German potash even if he might obtain it a little bit cheaper than the local product. In other words he must not be a potash slacker. The politician hates to take any action which would have a harmful effect on the farmer vote, so we may look for strong opposition when legislation is urged for protection of the new potash industry. It would be shortsighted if our Congressmen should fail or neglect fully to protect this industry. It should be remembered that Germany will continually strive to break down any barriers which may have been erected, and it therefore behooves us to band ourselves together in an alliance which could fittingly be called the American Potash Alliance and see to it that our interests are at all times being taken care of.

"In unity there is strength, therefore let all parties interested form such an alliance and immediately organize and institute efforts to have the proper legislation passed, and also to conduct a publicity and an educational campaign throughout the country and, generally, to serve the combined interests of those who assist in rendering our country free from the Kaiser as far as potash is concerned. The hearty and active coöperation of the various technical societies should be readily obtained, and I commend these suggestions for the formation of the American Potash Alliance to their attention."

## Sidelights on the Exposition

The New Jersey Zinc Co. has a bull's eye on its drawn zinc rods and wire. This is made of very pure metal and, as shown by the exhibit, it machines well and may be turned and used for fittings of various kinds in the place of brass. It may be polished and lacquered, but if this surface will not do, they even show a sample of it that has been gold-plated. Little difficulties should not stand in the way of progress. Another way to avoid the use of brass as displayed by this company is by sherrardizing small iron castings such as are used in building hardware. Another N. J. zinc bull's eye is on zinc oxide, U.S.P., now made in large quantities for the first time in this country.

\* \* \*

Another metal-saving possibility is shown by the National Gum & Mica Co. in a method of coating paper containers with a colloidal solution of tin and afterward burnishing it into a very thin colloidal film. The back of the paper is coated with paraffin to augment its merit, and the front looks like tin. Still another new thing is a high-speed gum whereby long paper cylinders may be turned out by machinery without the usual gooev difficulties, and these are then cut into desired lengths for boxes. And another bull's eye is attached to Mr. Jerome Alexander's new colloidal silver which will doubtless find its main use as a drug, in the treatment of diseases of the mucous membranes. For certain of these, silver in a very finely divided state seems to be a specific. If applied in the form of silver nitrate or in its presence, an artificial membrane or coagulum is produced over the places where the micro-organisms have bored themselves in and where they proceed unharmed in their nefarious business. It appears that this defect has been overcome in Mr. Alexander's invention.

\* \* \*

The grape-juice girls are on hand again, all over the Palace, selling the beverage at ten cents *per*, in sterilized paper cups. It is excellent grape juice, and we observed but two criticisms upon it among all the thousands present. One was from a stout, red-faced man who declared, as he stood drinking it, that it had an "unfinished" taste. If it had been finished as he desired it we are convinced that the internal revenue officers would soon have been worrying the girl that sold it. The other criticism was by example rather than by precept: across the way from the stand is the booth of the Celite Products Co. where samples are shown in pairs, to exhibit various products before and after filtering through their filters. These include lemon oil, soap, lye, kola tonic, molasses, apple cider, castor oil AND grape juice among many other things. The clear, ruby, filtered grape juice serves well the purposes of the exhibitors, but we have no faith in its appeal to the stout man with the red face. No amount of filtering would give it the "finish" that he desired.

\* \* \*

The American masks have the merit of being effective against lethal gas even when the face-piece is torn or cut, although in this event of course the soldier would not be immune against torture gases.

A Freudian philosopher was observed contemplating the U. S. Army mask for horses. "Here we see," he

exclaimed, "the evidence of a wish on the part of the designer which is apparent to every true Freudian. He wanted to be in the woods, hunting big game, instead of doing the work in hand, because he has unconsciously made the horse to resemble a moose!" There certainly is nothing like Freudian philosophy for boring into the other fellow's soul!

\* \* \*

The chemical-warfare exhibit is distributing "literature," which means copies of rules and general orders relating to chemists and engineers in essential industries. It will surely be a great convenience to manufacturers who are so engaged because here they may obtain concrete information. The orders are very direct and simple: they are written to be understood and obeyed, and not quibbled over. There are rules for the allocation of enlisted men to industry, which means getting men out of the ranks and back into the works. It can be done but it isn't easy and it doesn't look profitable to undertake unless the industry is "essential to the prosecution of the war," and the man's work cannot be done by any other man or woman. It doesn't seem so many years ago when the most dreadful thing that could happen was the loss of money to a corporation. The War Department does not seem to consider it in this light. What mustn't happen is keeping men out of the army without good and sufficient reasons.

Many men are needed in industry far more than they are needed in the ranks, and yet they feel ashamed not to be in the army. They want to feel that they are in the fight and in it with a gun. Sometimes an impelling reason for their unrest has been that when they returned home and went to work again in the factory they were called slackers. Instructions, therefore, have been issued for men on indefinite furlough, when such furlough is granted for periods to exceed three months, that the regulations as to uniform shall be the same for them as for honorably discharged enlisted men. They are authorized but not required to wear the service uniform, but it shall be furnished and maintained without expense to the United States. They must not wear it, however, while performing manual labor.

This rule sounds pretty good to us. If men are teased for not being on the firing line they can put on their uniforms and stand forth in them in all the dignity of a soldier of the United States.

\* \* \*

Of course, everybody knows how to run a bank, a railroad or a newspaper. This is confirmed by the frequent criticisms of banks, railroads and newspapers that we hear on all sides from nearly everybody, with specific details as to what should be done that it left undone and wherein capital errors lie. And yet, there are little details in banking that require study and experience — just as we find this need in chemistry. So the Irving National Bank of New York has taken a booth at the Exposition and Mr. Dimse, their representative, says that it bids fair to be abundantly worth while. The inquiries in regard to banking facilities, more particularly as to export trade, are frequent and sincere, and opportunities to get posted in regard to acceptances, foreign exchange and a considerable series of other subjects are provided for by numerous pamphlets issued by the bank.

## From A to Z With the Exhibitors

**AIR REDUCTION CO.** An exhibit of compressed oxygen, acetylene, nitrogen, hydrogen, gas welding supplies, ammonia, cyanides, formates, ferro-cyanides, Paris blue and Turnbull's blue. In charge of exhibit: R. T. PEABODY, MISS L. E. MARRS.

**ALBERENE STONE CO.** Complete chemical laboratory hood, the superstructure of hood being Alberene stone; table top, reagent shelves and sink. In charge of exhibit: A. Y. MEEKER, W. K. FIELDS, N. N. MONEY-PENNY, R. J. NYCE.

**AMERICAN PIPE BENDING MACHINE CO.** A Model S Junior and a Model A standard "Wonder" pipe bending machine. In charge of exhibit: E. P. BLAKE.

**ANACONDA COPPER MINING CO.** An exhibit of copper bars, cathod, anode billets, sulphate and blister copper together with selenium, tellurium, nickel sulphate, zinc and silver. In charge of exhibit: S. SKOWRONSKI.

**H. REEVE ANGEL & Co., INC.** Whatman analytical and American industrial filter papers; Labruco rubber tubing. In charge of exhibit: ERNEST CHILD.

**ANTI-HYDRO WATERPROOFING CO.** A non-corrosive concrete waterproofing. In charge of exhibit: M. D. HAUSLING.

**BACHMEIER & Co.** Dyestuffs as follows: Congo red, aniline black, patent blue; Baco direct rose and pink, which is fast to acid; acid fast red, direct yellow, methyl violet, direct blue, sulphur black, sulphur khaki and chrysophenine. In charge of exhibit: E. J. STRUCK, MARSDEN LORD.

**J. T. BAKER CHEMICAL CO.** Laboratory analysed chemicals, organic acids, barium, copper, cobalt, ferric lead, magnesium, manganese, nickel, potassium, sodium salts, etc.

**THE BARBER ASPHALT CO.** Samples of Genasco roofing, shingles, mastics, waterproofing, paints and varnishes, Genasco asphalt putty, Genasco mineral rubber, Trinidad and Bermudez Lake asphalts, Gilsonite, acid-proof mastic tank linings. In charge of exhibit: E. J. CARLEN, A. S. LEWIS, THEODORE THOMAS.

**THE BARRETT CO.** An exhibit of the Chemical Department which includes coal tar products, toluol, ammonia, paracumaron resins, phenol, benzol, cresols, pyridin, naphthalin, resorcin, B.R.C. rubber filler. In charge of exhibit: H. G. SIDEBOTTOM.

**BOYER OIL MFG. CO.** An exhibit of oils, including cottonseed, castor, soya bean, peanut, sesame, cocoanut, rape seed, palm kernel, china wood, palm, poppy seed and all oil cakes. In charge of exhibit: W. G. REED.

**BROWN INSTRUMENT CO.** Thermometers and recording gages. They will exhibit specially encased instruments which are protected from fumes, dirt, etc. In charge of exhibit: GEORGE W. KELLER.

**BUFFALO FOUNDRY AND MACHINE CO.** An extensive exhibit showing expansion tanks, evaporators, nitraters, vacuum dryers, vacuum pumps; high concentrator, vertical tube evaporators; horizontal tube evaporators and rapid circulation evaporators. In charge of exhibit: E. G. RIPPEL.

**CANADIAN ELECTRODE CO.** Carbon electrodes.

**CANADIAN ELECTRO PRODUCTS CO.** Acetic acid, acetaldehyde, paraldehyde, acetone, sodium acetate, mercuric oxide.

**CELITE PRODUCTS CO.** Filter-cel, sil-o-cel, high-temperature insulation, and celite, also samples of clarified oils. In charge of exhibit: W. S. COLLINS.

**CHEMICAL PUMP AND VALVE CO.** Lead and stoneware pumps. In charge of exhibit: F. A. WARTER.

**CONSOLIDATED COLOR & CHEM. CO.** Gallocyanine (fast navy blue), sulphur dyes, chrome dyes. In charge of exhibit: H. A. METZ.

**CONTACT PROCESS CO.** Sulphuric acid, 50 deg., 60 deg. and 66 deg.; oleum, 20 per cent; nitric acid, muriatic acid, salt cake and niter cake.

**CORNING GLASS WORKS.** Laboratory glassware, Pyrex and colored signal light glassware. In charge of exhibit: G. W. DRAKE.

**CRANDALL PETTEE CO.** Gas and electric automatic baking and drying ovens. In charge of exhibit: PAUL DELANY.

**CRESCENT INK & COLOR CO., INC.** An exhibition showing how ink is made. In charge of exhibit: N. A. MCMANUS, JOSEPH M. PETRY, WALTER A. CONLAN.

**DOW CHEMICAL CO.** Samples of chemical products manufactured by the company. Since entering the war this company has developed and perfected on a large scale the process of synthetic indigo 20 per cent, paste and dibrom-indigo 20 per cent. paste. The product is pronounced equal in every way to that imported from Germany before the war. Diethylaniline is also being manufactured on a commercial basis.

**DUPONT & Co.**—The space occupied by the duPont Company is the largest ever occupied at the Chemical Exposition. The exhibit shows most of the 300 products made by the company. For the first time there is displayed a rather complete lot of dyes which have been manufactured during the past year. The Arlington Works division exhibits a line of high-class toilet articles made from ivory pyralin. In charge of exhibit: R. L. VILAS, STANLEY F. WHITE, J. A. GWYN.

**DURIRON CASTINGS COMPANY.**—A line of pumps, cocks, valves, pipe, kettles, exhaust fans, nitric acid condensers, bleacher pots, denitrating towers and Hough sulphuric acid concentrators. The latter has been on the market since the United States entered the war. It is built along entirely new lines and is applicable to most processes where evaporation is required. In charge of exhibit: J. R. PITMAN.

**EDISON INTERNATIONAL CORPORATION.** Coal-tar products; chemicals; drugs. Paraphenylenediamine is featured in the exhibit. In charge of exhibit: T. C. LEMLEY, J. D. LYMAN, W. C. WETMORE, E. P. MOUSIR.

**THE ELECTRIC FURNACE CO.** Exhibition of photographs and drawings of furnaces that are producing war materials, such as airplane parts, billets for shells, melting furnaces for airplane and submarine castings. In charge of exhibit: D. D. MILLER.

**ELECTRO BLEACHING GAS CO.** Manufacturers of liquid chlorine. In charge of exhibit: J. A. KIENLE, D. K. BARTLETT.

**ELECTROLYTIC ENGINEERING CORP.**—The Wheeler process for the manufacture of caustic soda and liquid chlorine will be exhibited by means of photographs and cross-sectional views to show the details of the cell and process. In charge of exhibit: R. G. KEHOE.

**ELECTROLYTIC ZINC COMPANY.** An exhibit of zinc

products. In charge of exhibit: S. G. SCHATZBERG, A. W. HAHN, W. H. NAUGLES.

**ELECTRON CHEMICAL CO.**—A complete cell for the electrolytic production of chlorine and caustic soda, together with photographs illustrating some installations. In charge of exhibit: HERBERT I. ALLEN.

**G. H. ELMORE.**—Acid-proof centrifugal pumps, with blueprints showing interior arrangement. Blueprints of centrifugal driers. **BLAIR CAMPBELL & MCLEAN, LTD.**, from Glasgow, Scotland, are associated with Mr. Elmore in this exhibit, but on account of the scarcity of cargo space it has been impossible to secure specimens of their chemical apparatus for exhibition purposes. In charge of exhibit: G. H. ELMORE, R. W. RIGLER, A. C. WOOD, For **BLAIR, CAMPBELL & MCLEAN, LTD.**, JAMES C. LAWRENCE.

**ELYRIA ENAMELED PRODUCTS CO.**—Elyria cast iron glass-enameled equipment, including a 125-gallon still, 125-gallon open jacketed kettle, 35-gallon kettles, 2-gallon stills and autoclaves. Practically all of the cast iron apparatus has been developed since the beginning of the war, due to the great demand occasioned for such apparatus formerly furnished by foreign makers. In charge of exhibit: WM. E. GRAY.

**EMPIRE CHEMICAL CO.**—This exhibit consists mainly of saccharine. In charge of exhibit: S. J. NATHAN.

**EMPIRE LABORATORY SUPPLY CO.**: Glass apparatus manufactured at Vineland, N. J. This company is making glass apparatus which formerly came from Germany. In charge of exhibit: PHILIP FREEDMAN, M. A. GOLDSTEIN.

**EVERLASTING VALVE CO.**—"Everlasting" valves in all sizes from 16 in. to 1 in., arranged in pyramid about 40 in. diameter at the base and extending 13 or 14 ft. from the floor. Everlasting tandem valves. In charge of exhibit: EDWARD N. CORNING.

**W. L. FLEISCHER & CO., INC.**—Small-scale model of a warm moist air dryer, built especially for the drying of chemicals, fruits and vegetables. This will be an exact model, complete in every detail. It has been developed entirely since our country entered the war. In charge of exhibit: R. E. KEYES, A. W. LISSAUER.

**FOOTE MINERAL CO.**: Various mineral products and their derivatives as well as ores and compounds of the rarer elements including zirkite, antimony trisulphide, manganese dioxide, zirkite bricks, cerium-iron alloy, ammonium molybdate and molybdic acid, strontium sulphate, titanellow colors and zirkonalba. A feature of the exhibit is the projection of bright line and absorption spectra of the rare element salts, as well as processes of crystallization. In charge of exhibit: H. C. MEYER.

**FOXBORO CO., INC.** A temperature controller, CO. recorded and recording pyrometer all in operation; recording hydrometers, planimeters, time recorders, gage boards with instruments, CO. recorders, indicating and recording thermometers; gages, pressure, syphon, mercury, vacuum and liquid level; pyrometers; revolution counters. In charge of exhibit: W. W. PATRICK, M. B. HALL, L. H. DUPAUL.

**FULLER-LEHIGH COMPANY.** A model of the Fuller-Lehigh pulverizer mill, with samples of chilled charcoal iron castings for abrasive resistance. In charge

of exhibit: C. R. RINEHART, E. H. FROMM, W. A. STURBLEBINE, G. D. MEASE, P. F. STUFFER.

**CHAS. F. GARRIGUES CO.**: A display of chemicals and special exhibits of caustic potash, stearate of zinc and sulphur dioxide. In charge of exhibit: OTTO F. ANDERSON and other representatives.

**GENERAL BAKELITE CO.**—Bakelite raw materials and finished products made from same. The raw materials include moulding material, lacquer, varnish, cement and enamel. The finished products show a wide range of mechanical and electrical articles made from various bakelite moulding materials. The application of lacquer, protective enamel and cement is also shown. Bakelite rods, sheets and tubes manufactured from bakelite canvas and paper is featured in the exhibit. Numerous other articles are shown which have become more or less well-known to the general public, such as pipe-stems, umbrella handles, fountain pens, etc. In charge of exhibit: HYLTON SWAN.

**GENERAL CERAMICS COMPANY**—Armored stoneware centrifugal pumps, armored stoneware exhauster, machine for etching copper plates by nitric acid, stoneware automatic acid elevator. In addition to the foregoing which will be shown in operation, there will be a model of the Valentiner nitric acid installation which has been adopted by many of the belligerent countries, as well as many of the large industrial concerns here and in Europe. All of this material has been developed in this country since the war for the first time. In the exhibit will be one of the largest stoneware vessels ever manufactured in this country, although not the largest manufactured by this company. There will also be miscellaneous stoneware equipment, a new tower filling, and a variety of small shapes for high-temperature work. In charge of exhibit: PERCY C. KINGSBURY, F. A. WHITAKER, K. J. PETERS.

**GENERAL CHEMICAL COMPANY**—Commercial and C. B. acids and ammonia, reagents, acetyl chloride, copper sulphate, iron salt, lead acetate, magnesium sodium and tin salt, zinc sulphate, "Orchard" brand of insecticides and fungicides, and "Lariat" brand cattle dips, and "Ryzon" baking powder. In charge of exhibit: N. PETERKIN and members of sales staff.

**GENERAL ELECTRIC COMPANY**—Flow meters for measuring steam, water, air, oil and gas. A long list of processes and commodities relating to the chemical industry, developed in the company's research laboratory. The diversity of the activities of the laboratory is indicated in the variety of the exhibit, which covers improved lighting, radio apparatus, searchlights, X-ray apparatus, Coolidge tubes, water japsans, metals, alloys, chemical compounds and smoke precipitation. In charge of exhibit: L. W. SHUGG and other representatives of the company.

**GENERAL FILTRATION COMPANY**—Filtros plates in various sizes, grades and shapes, being uniformly porous and acidproof, are finding extensive use in the chemical industry. The porosity of the material will be demonstrated by forcing air through a plate which has been saturated with water. Electro-filtros, a porous acidproof diaphragm, will be exhibited in electrolytic cells of various sizes. In charge of exhibit: F. E. LEIBY.

## Potash from Searles Lake\*

An Account of the Development of a Project for the Recovery of Potash from the Saline Water of a California Lake—The Product Contains Sixty-Five Per Cent Potassium Chloride

By ALFRED DE ROPP, JR.

Research Engineer American Trona Corporation

FOR the following topographical description of the Searles Lake Basin and its porous salt bed, I am indebted to *Bulletin 580-L*, written by Hoyt S. Gale of the United States Geological Survey.

FIG. 1.—MAP OF THE CALIFORNIA SALINE LAKES

His description of Searles Lake and the surrounding country is the clearest and most comprehensive of

any that have come to our notice. Fig. 1 shows the location of California saline lakes, and Fig. 2 their respective elevations.

Searles Lake Basin is a broad, roughly circular valley or depression eight to ten miles from east to west and twenty to twenty-five miles from north to south, bordered by the abruptly rising slope of the surrounding ranges. This basin lies between the Argus Range on the west and northwest, and the Slate Range on the east; the latter a narrow, rocky wall, which divides it from the larger and deeper depression of the Panamint Valley.

The Searles Lake Basin was, during a part of the glacial epoch, occupied by at least one deep lake, whose traces are still so distinct as to be indisputable.

While the waters stood at their highest position the Searles Basin was flooded to a depth of 635 to 640

FIG. 2. PROFILE SURVEY CROSSING LAKES

feet above the level of the present valley bottom, and the lake extended back through the Salt Wells Valley to join with a broad, shallow lake that flooded the greater part of the Indian Wells Valley.

With the lowering of the water-level less than seventy-five feet, the divide in the volcanic peaks between Indian Wells Valley and Salt Wells Valley became an actual division between two distinct water bodies, and for a time here also there was a period of overflow from Indian Wells Valley to the lower waters in the Searles Basin, in the same way that Owens Valley overflowed and spilled its waters into Indian Wells Lake. These are facts attested to by the records of the ancient shore lines and water channels.

The determined elevation of the lowest part of the present salt flat in the main Searles Basin is 1,617.6 feet above sea level.

\*A Paper read at the Fourth National Exposition of Chemical Industries, New York, Sept. 25, 1918.

The Owens Lake, during a period of former greater water supply, overflowed the divide at the south end of its basin and its surplus waters flooded in turn a succession of lower basins, of which the Searles Basin was one of the largest.

The Owens waters, after passing the Haiwee Divide, dropped some fifteen hundred feet in about thirty miles to Indian Wells Valley, and then spread out in a broad and relatively shallow sheet of water. This, in turn, also overflowed, its waters passing by way of Salt Wells Valley and a rock cut gorge at the lower end of that valley into the Searles Basin.

Eventually, the waters rose in the Searles Basin to

level of the brine in the lake at any one spot to a noticeable extent.

The main or central salt deposit is a firm but extremely porous bed of salt crystals, so hard and compact that roads are built on it, teams and motor trucks have no difficulty in driving over its surface, and even the concrete foundations of the American Trona Corporation's pump house were laid on the surface of the crystal body.

The first fifteen to twenty feet of the crystal body is composed of cubical halite and will analyze 90 per cent (or better) NaCl on a dry basis. Below this are alternating and irregular layers of salts, respectively

FIG. 3.—CROSS-SECTIONS OF SEARLES SALT DEPOSIT

such a height that all three of these valleys were submerged in one continuous body of water. The maximum water level in this basin was clearly determined by the elevation of an outlet pass on the south side of the basin, whence its surplus waters flowed into the extreme south end of Panamint Valley.

In the Panamint Basin a history similar in some respects to that of the Searles Basin was repeated. The waters rose until the height of the lowest outlet was reached, and as they evidently remained stationary at about that level for a relatively long period, it is presumed that this level was determined by the overflow of its surplus waters.

#### SALT DEPOSIT PROSPECTED BY DRILLING

The most distinctive feature of this desert basin is the immense sheet of solid white salts that lie exposed on its bottom. It is to this salt deposit that the name Searles Lake has been generally applied. So far as known, at present the deposit is unique in this country in the variety of its saline minerals.

Fig. 3 shows two cross sections of the crystal body. These were plotted from data obtained from the numerous wells which were drilled by the California Trona Company to comply with the assessment work necessary to hold its claims. Some 300 wells were thus drilled.

As may be seen, the crystal body underlies the surrounding mud flats found along the shores of Searles Lake.

The area of salt crust in the Searles Basin is some twelve square miles in extent, and averages from 65 to 75 feet in depth. The formation of the crystal body is such that the brine with which it is associated is absolutely free-flowing, and nowhere, even by extended pumping operations, have we been able to lower the

high in trona, a sesquicarbonate of soda, sodium chloride, and sodium sulphate. The potash content of these layers is very irregular, layers of potash bearing crystals having been discovered by various drilling operations, which ran from fourteen to thirty-odd per cent potassium chloride. (The average potash content of the crystal body is roughly 4 per cent potassium chloride.)

In a report made to the American Trona Corporation by Charles S. Lee it is estimated that the crystal body contains 110,000 million gallons, or 594,000,000 tons of brine. This does not include any incoming waters from either underground or surface sources. This brine will average 4 per cent potassium chloride. The potash contained in this brine amounts to 23,760,000 tons of potassium chloride.

The average brine pumped by the American Trona Corporation has the composition given in Table I.

TABLE I—AVERAGE COMPOSITION OF BRINE

|                 | Per Cent |
|-----------------|----------|
| Na              | 11.00    |
| K               | 2.50     |
| Cl              | 12.50    |
| CO <sub>2</sub> | 2.65     |
| NO <sub>3</sub> | 4.65     |
| B               | .35      |

In view of the process in use, the brine is given the arbitrary composition shown in Table II based on the values in Table I.

TABLE II—COMPOSITION OF BRINE BASED ON VALUES IN TABLE I

|                                               | Per Cent            |
|-----------------------------------------------|---------------------|
| NaCl                                          | 16.50               |
| Na <sub>2</sub> SO <sub>4</sub>               | 6.90                |
| Na <sub>2</sub> CO <sub>3</sub>               | 4.70                |
| Na <sub>2</sub> B <sub>4</sub> O <sub>7</sub> | 1.50                |
| KCl                                           | 4.75                |
| Specific Gravity                              | 1.290 at 30 deg. C. |

All the CO<sub>2</sub> is figured as normal carbonate, although the brine contains some bicarbonate. This brine is pumped to the plant from wells drilled in the crystal

body of Searles Lake. The brine is pumped to storage tanks and from them directly to the evaporators. It passes first through a 16-foot Manistee vacuum pan, which is used merely as a pre-heater. From this it is pumped to three 22-foot pans of the same type, which are operated in triple effect.

The pans handle from 200,000 to 250,000 gallons of raw brine and about 100,000 gallons of mother liquor

FIG. 4.—PUMP HOUSE BUILT ON SALT DEPOSIT

per twenty-four hours. This total of 300,000 to 350,000 gallons of liquor is concentrated to about 100,000 gallons of "concentrated liquor" before being sent to the crystallizing house to cool.

During the boiling, sodium chloride, sodium sulphate and sodium carbonate are salted out. These tailing salts drop to the bottom of the vacuum pans and are removed by salt elevators of the regular Manistee type. The elevators discharge their salts into waste salt cones from which they are washed away by water.

Machinery is being installed by Dr. H. W. Morse, technical manager for the corporation, by which we will recover 95 per cent of the potash formerly carried away by these waste salts. This will increase our output by some ten tons (or better) of potassium chloride per unit per twenty-four hours. Operating under the old system this was previously lost to us.

EVAPORATION AND CRYSTALLIZATION

The liquor in the pans is boiled down to the point where potassium chloride begins to salt out, and is then sent to crystallizing vats in this condition at a temperature of 90 to 95 deg. C.

The temperatures and vacua are about as follows:

| Pan No. | Vacuum, In. | Temp., Deg. C. |
|---------|-------------|----------------|
| 4 ..... | 24.5        | 50-55          |
| 3 ..... | 24.5        | 50-55          |
| 2 ..... | 21.0        | 70-75          |
| 1 ..... | 12.5        | 90-95          |

The triple-effect pans are operated with constant flow, liquor entering the pan next the vacuum pump (where the vacuum is highest and the boiling point lowest) and passing in a constant flow from this pan through

the intermediate pan to the final high-temperature, low-vacuum pan, and from this pan to the crystallizing vats.

Cooling and crystallization take place in crystallizing vats 54 by 15 by 6 feet. There are 36 such vats in the unit now operating, and the day's run of hot concentrated liquor fills from three to four of these. The vats cool for about eight days, and the liquor, now nearly at atmospheric temperature, is then drained off.

The crystal crop is shoveled into a traveling box and is carried to a drain floor, where it is allowed to lie for about a week or so before shipment.

COMPOSITION OF RAW MATERIAL AND PRODUCTS

Table III gives the average composition of raw brine,

FIG. 5.—ROAD CROSSING SALT DEPOSIT

concentrated liquor, mother liquor returned to the system, and crude potash salts ready for shipment:

TABLE III.—PERCENTAGE COMPOSITION OF RAW MATERIAL AND PRODUCTS

|                                                     | Raw Brine | Concentrated Liquor | Mother Liquor | Crude Potash Salts |
|-----------------------------------------------------|-----------|---------------------|---------------|--------------------|
| Na <sub>2</sub> B <sub>4</sub> O <sub>7</sub> ..... | 1.50      | 8.81                | 7.82          | 10.91              |
| Na <sub>2</sub> CO <sub>3</sub> .....               | 4.70      | 10.82               | 10.53         | 1.70               |
| NaCl .....                                          | 16.50     | 9.67                | 9.43          | 10.93              |
| Na <sub>2</sub> SO <sub>4</sub> .....               | 6.90      | 2.58                | 2.08          | 0.44               |
| KCl .....                                           | 4.75      | 14.87               | 10.82         | 66.34              |
| H <sub>2</sub> O .....                              |           |                     |               | 9.66               |
| Total .....                                         | 34.35     | 46.75               | 40.68         | 99.98              |
| Sp. Gr. at .....                                    | 1.290     | 1.384               | 1.362         |                    |
| Temperature, Deg. C .....                           | 30        | 38                  | 34            |                    |

The American Trona Corporation is producing to date some 1800 tons of crude potash salts a month. Additional equipment, such as a nearly completed second unit, together with a 300-ton ice plant for refrigerating purposes and new methods for treating the concentrated liquor (devised under the direction of Dr. H. W. Morse) will enable the American Trona Corporation to produce by the end of October some 4500 tons

of potash salts a month, analyzing from 75 to 80 per cent potassium chloride and containing less than 3.5 per cent borax, figured as anhydrous sodium tetraborate.

By the first of 1919 the American Trona Corporation will be producing some 40 to 50 tons of refined borax daily analyzing 99.50 per cent  $\text{Na}_2\text{B}_4\text{O}_{10}\text{H}_2\text{O}$ .

#### PUMP HOUSE, TRANSFORMER STATION AND MANIFOLDS

The pumping equipment consists of two all-iron centrifugal pumps each capable of delivering 750,000 gal-

Vergne ice machines, driven by three Corliss engines of 300 hp. each.

#### TRONA REEF, NORTHEAST END OF SEARLES LAKE

The company owns some seven hundred acres of claims here. The high grade trona in these claims amounts roughly to 40,000 tons. Besides this there are some 20,000 tons of a lower grade trona comprised in these claims.

The American Trona Corporation has built a raised road completely across the lake, connecting the Trona

FIG. 6.—GENERAL VIEW OF PLANT

lons of brine per twenty-four hours to the company's storage tanks. The pumps are connected by short manifolds to six wells drilled through the crystal body.

The pump house and a raised road on which is operated a narrow-gage, gasoline locomotive and dump cars, are built directly on the surface of the crystal body, as shown in Figs. 4 and 5. Our assay map of the crystal body has shown us that this is the most favorable location for our pumping plant.

The road built out to the pump house is about three and one-half miles long. Between 19,000 and 20,000 feet of ten-inch iron pipe connects the pumps with two storage tanks of 500,000 gallons capacity each. The pipe line is laid on concrete piers. It is insulated against changes in temperature by a two-inch layer of hair felt and a one-inch layer of wool felt, the insulation being protected against the elements by a thin sheet of black iron, which is fastened by narrow iron straps.

In Fig. 6 is shown a general view of the plant. At the left are the storage tanks. Next is the boiler plant containing 12,500 hp. Babcock & Wilcox boilers, which supply steam for operating the steam turbines; high-pressure water pumps for the Pelton water wheel drives on the pumps; elevators and propeller shafts of the evaporators, and the Corliss engines which drive the ammonia compressors in the new refrigerating unit. The exhaust steam from these turbines and steam engines is fed to the evaporators.

The Pelton water-wheel drives having proved costly and inefficient to operate, the new management is replacing them with electric drives, thus effecting a considerable saving in oil.

Between the boiler houses and evaporator buildings rise concrete chimneys, 15 ft. high and 9 feet in diameter in the clear on top. The two evaporator buildings will house, when completed, two triple-effect 22-foot diameter Manistee vacuum pans, and two double-effect 16-foot diameter pans of the same design. To the right may be seen the crystallizing house, 180 feet wide and 800 feet long.

The equipment in the refrigerating unit which is under construction consists of three 100-ton De La

Railroad with its Trona claims by a narrow gage, gasoline operated railroad.

#### BRINE STORAGE AND EVAPORATION

The storage tanks shown in Fig. 7 contain a combined capacity of one million gallons or 650 tons. From them the brine is pumped to the evaporators shown in Fig. 8.

These pans stand 86 feet high and are 22 feet in diameter. The calandria or steam belt is comprised in the first section above the working floor, which is thirty feet above the ground floor of the building. Reading from left to right, the pans are numbered 3, 2 and 1.

No. 3 is the low-temperature, high-vacuum pan and it is into this pan that the brine after a pre-heating

FIG. 7.—BRINE TANKS

in a single-effect 16-foot Manistee pan is pumped, together with a proportionate amount of mother liquor from the sumps in the crystallizing house.

The liquors pass from No. 3 pan through the intermediate No. 2 pan into the high-temperature, low-vacuum No. 1 pan in a steady flow. From No. 1 pan the now concentrated liquors, having a specific gravity of 1.385 to 1.390, are pumped over to the crystallizing house. Exhaust steam from Terry steam turbines is fed to No. 1 vacuum pan from a mixing drum.

To the left of No. 3 pan is shown a rotary jet condenser. This pump, operated by a 500 hp. Terry steam turbine, functions both as a vacuum pump and condenser, handling the vapor from No. 3 pan. The condensed vapors and cooling waters are pumped from the condenser and returned to the spray pond by an auxiliary booster pump. Some 7000 gallons of condensed and

FIG. 8.—BATTERY OF MULTIPLE EFFECT EVAPORATORS

cooling waters are forced through the sprays every minute.

#### UPPER FLUE SHEET OF A 22-FOOT MANISTEE VACUUM PAN

The men shown in the photograph, Fig. 9, are expanding the two-inch diameter, six-foot charcoal-iron flues into the upper flue sheet of the calandria.

FIG. 9.—UPPER FLUE SHEET OF CALANDRIA

22-foot pan contains about three and one-half miles of such flues.

A propeller shaft, extending through the length of the pan from the top of the pan to well below the calandria, and making thirty revolutions per minute, increases the circulation of the heavy pan liquors through the flues; heavy mineral oil prevents foaming.

In Fig. 10 are shown the evaporator leg pipe and tailings elevator. These tailings-salt elevators handled roughly 350 tons of waste salts per twenty-four hours. These salts are dropped by gravity into waste-salt cones

FIG. 10.—EVAPORATOR LEG PIPE AND TAILINGS  
ELEVATOR

from which they are flushed with brackish water back on to the lake.

In the background of Fig. 11 may be seen the Pelton-Doble water-wheel-driven pump with its set of connections for filling and draining the vacuum pans. It has a

FIG. 11.—PUMPS FOR CHARGING BRINE TO EVAPORATORS

capacity of 6000 gal. per minute. The suction and discharge openings are 16 inches in diameter.

By opening any two of the six valves shown in Fig. 12, the pans may either be filled with raw brine prior to starting a run; drained into large storage vats prior

FIG. 12.—VALVES CONTROLLING THE BRINE LINES

to boiling out (which in the present cycle is done after every run of thirty-six hours); filled with brackish water for boiling out to clean pans; or drained of same after boiling out has been accomplished. The rotary

jet condenser used on the "high vacuum" pan is illustrated in Fig. 13, showing reduction gears and the 500-hp. Terry steam turbine for driving them. The booster pump for removing cooling and condensed waters is in the background.

FIG. 13.—ROTARY JET CONDENSER

Fig. 14 shows a triple-effect unit of 22-foot Manistee vacuum pans as they appear when completed. They are insulated with two-inch corrugated air cell asbestos. On top of this is spread a layer of plaster about one inch thick, and on top of this is a covering of 10-oz. duck, the whole being finished off with a coating of white paint.

In the distance may be seen a part of the 16-foot

FIG. 14.—VACUUM EVAPORATORS SHOWING INSULATION

single-effect pan now used as a pre-heater for the raw brine fed to the No. 3 pan.

The interior of the crystallizing house is shown in Fig. 15. This picture shows two of four rows of crys-

FIG. 15.—VIEW OF CRYSTALLIZING VATS

tallizing vats. These vats are 54 feet long, 15 feet wide and 6 feet deep. They hold 30,000 gallons of concentrated liquor. An average of 15 tons of crude potash salts is taken from each vat. There are 36 such vats in use for the one unit which is now operating.

#### POTASH IN THE CRYSTALLIZING VATS

It takes from seven to eleven days for a vat to cool to near atmospheric temperature, depending on the time of the year. At present, during summer weather at Searles Lake, the vats are dropped at from 40 to 45 deg. C. In the winter when the nights are very cold

FIG. 17.—POTASH STORAGE FLOOR

the temperature of the vats drops more quickly, and the mother liquor is returned to the system at from 25 to 30 deg. C.

All of this has a big effect, not only upon the quantity and nature of the salts produced, but it also has a big effect upon the actual operation of the vacuum pans themselves.

The crude potash salts are carried from the vats to the drain floor in boxes of 2000 pounds capacity, which are operated by self-propelled electric hoists. The potash stays on this drain floor for about seven days before it is passed through a Stedman mill prior to being loaded for shipment.

Trona, Cal.

FIG. 16.—REMOVING POTASH FROM CRYSTALLIZING VAT

#### Zeolites as Potash Collectors

ACCORDING to Dr. F. W. Clarke, in the Data of Geochemistry, U. S. Geological Survey *Bulletin* 491, the average proportion of potassium to sodium in river waters is as one to four, while in sea water the ratio is one to thirty. In igneous rocks sodium and potassium are nearly equal, and in view of the greater solubility of most of the potassium salts it would seem as if the mysterious disappearing process began as soon as the rocks weather. The reason for this, as given by the same authority, is that ordinary soils, and more particularly clays, are able to remove a considerable proportion of potash salts from their solutions and that these are removed from natural waters as they percolate through the soil, or by the suspended silt carried through the streams. The sodium is not so largely withdrawn, so that its relative proportion in solution increases. Thus the metal with more soluble salts is deposited with the sediments while that with less soluble salts remains in solution. Experiments on Hawaiian soils by Crawley and Duncan show that a layer six inches thick will fix over 98 per cent of the potassium in a solution of potassium sulphate which is allowed to filter through it.

This feature of zeolites would point to a method of collecting potassium from river waters were it not for the fact that calcium and magnesium take precedence over alkali metals and that the latter form their substitution products only under mass action.

In analysis of red clay from ocean bottoms made on the Challenger expedition and later confirmed in the laboratory of the U. S. Geological Survey, it was noted that potassium was commonly but not always in excess of sodium. How to get these deposits up a mile or more from the floor of the sea would require the wit of another Herman Frasch, and even then the potash content of less than three per cent is not industrially promising. Glauconite, which is a hydrated silicate of potassium and ferric iron, is widely disseminated upon the sea bottom but most abundantly near the mud line surrounding continental shores. It is also found in the New Jersey green sands and it would hardly seem worth while to go under water for it when it may be found on dry land.

## Extraction of Potash from Kelp\*

BY C. A. HIGGINS

THE recovery of potash from kelp, and the utilization of kelp ashes, principally as a fertilizer, is an art that has long been practiced. Many centuries before the German Syndicate began to market potash salts from their Stassfurt mines, the crofters around the rocky shores of Scotland and the Northern Coast of France had burned the drift kelp as a fuel and scattered the ashes over their land as a fertilizer. The great success which resulted from the use of this kelp ash on the land caused a rapid expansion in the business of kelp harvesting, until about the beginning of the 19th century, quite a flourishing industry had already sprung up.

The opening of the German potash mines, however, about the middle of the nineteenth century, began to flood the market with potash at a price far below that at which the old kelp burners could produce it, and although the kelp-potash industry still struggled along in isolated parts of the coast amongst the Scottish crofters, and to some extent in Japan, it may be said that the German production killed the kelp industry, which had up to that time attained fairly considerable proportions.

The outbreak of the present war, however, drove potash users to look for new sources of supply, and naturally one of the first to come to their attention was kelp. Previous to the outbreak of the war many writers had drawn attention to the huge perennial beds of kelp which grow practically uninterrupted all along our coastal waters on the Pacific side, from the Mexican line to Alaska, and around the scattered groups of islands which lie close to the California shore. These vast fields of kelp seemed to offer inexhaustible supplies of potash, which according to the preliminary survey made by the Government, bade fair to supply far more than the normal requirements of our country for the indispensable muriate of potash. All that remained was to devise economical means for harvesting these vast beds, and drying and reducing the kelp to a suitable condition for transportation and use as a fertilizer. Within a few months, therefore, of the cutting off of the German muriate, various large companies were prospecting the Pacific coast for suitable sites on which to erect plants for the harvesting and extracting of potash from the Pacific kelp.

### OLD AND NEW METHODS OF HARVESTING

The earliest attempts at harvesting were very crude and involved a good deal of manual labor. Men in flat-bottom scows would reap the weed by hand with large sickle knives and burn it in a rather primitive way. The ash was afterward sold to the big fertilizer companies at a price based upon the potash content, which generally ranged around 15 per cent K<sub>2</sub>O. Later, however, modern methods were installed for the harvesting of kelp. Large flat-bottom, steam- or gasoline-propelled scows were equipped with a mechanical reaping device and band conveyors which cut the kelp and conveyed it in one operation into the tanks aboard the harvesting vessel, at very much less expense than that involved in the old method of handcutting. These harvesters, when filled, then proceeded to shore under their

own power and discharged their contents into hoppers at the plant, which in turn fed series of mechanical dryers where the kelp leaves were dried and partly incinerated by passage through revolving drums heated by oil burners. The dried incinerated kelp leaves were then ground and sacked and ready to be shipped to the fertilizer factory. Some attention is paid in the drying process to insure that a minimum of the potash and nitrogen content of the kelp is lost by the destructive distillation effect of the drying equipment. That, briefly, is the method now in use in plants where potash is considered as the only valuable constituent of the kelp. Experience has shown, however, that this process of producing potash and realizing the values of kelp is very expensive, and will exist possibly just so long as the war and the present high price of potash last.

### HIGH COST OF POTASH FROM KELP MUST BE REDUCED BY BY-PRODUCTS

A few figures will show the status of the kelp-ash industry in this regard. Using the modern harvesting methods that I have already briefly touched upon, experience shows that it costs around \$1.10 to harvest and bring a ton of kelp leaves ashore. Analyses show that the average potash content of the raw kelp as harvested in California coastal waters is about 1.3 per cent K<sub>2</sub>O, which means that it costs about \$85 to bring in the green kelp equivalent of 2000 lb. of 100 per cent K<sub>2</sub>O. On top of this, of course, has to be added the costs of drying these kelp leaves, which contain about 90 per cent of moisture, and by reason of their gelatinous and cellular structure, present quite a problem in desiccation. All indications seem to point very clearly to the fact, therefore, that any industry which looks to the production of potash from kelp on a permanent peace-time basis, must reduce its cost very considerably, or produce valuable by-products in the same process which in turn will effect a reduction in the cost of the potash.

Along these lines certain investigators have suggested as far back as a century ago that the peculiar algal bodies present in kelp might be profitably recovered and used in certain directions in place of gelatin, for the sizing of paper and textiles, the proofing of cloth, and in the production of rubber substitutes and admixtures. Another interesting suggestion is that of Prof. T. C. Frye, who made a conserve by first leaching out the potash and soluble salts and afterwards soaking the kelp in cane sugar solution flavored with lemon. In Japan a kind of sour pickle with vinegar is made from the fleshy parts of the kelp. The kelp fibre when compressed and dried also forms a hard substance resembling ebonite or vulcanized fibre, and at least one concern is working along these lines at the present time. The production of by-product iodine from kelp, however, has long been a practical proposition, although hampered somewhat by the competition of by-product iodine from the Chilean nitrate fields.

The biggest practical advance in the economical production of potash from kelp was marked in the year 1915, when the Hercules Powder Co. started the construction of large gasoline-propelled marine kelp harvesters and a factory located near San Diego, California.<sup>1</sup> This equipment was designed primarily for the produc-

\*Report of an illustrated address at the Fourth National Exposition of Chemical Industries, New York, Sept. 25, 1918.

<sup>1</sup>Illustrated article in this journal, June 1, 1918.

tion of acetone, potash and iodine from kelp. Kelp as a source of acetone was something entirely new to chemical industry, and chemists all over the world have watched the growth and development of the undertaking with great interest. The plant since its inception has rapidly increased the number and range of its products, and placed upon the market some new materials which are full of industrial promise.

Reduced to its simplest terms, the basic principle of this process of kelp reduction lies in the destruction of the cellular tissue of the kelp leaf by fermentation, bringing the potash into solution, and producing acetic acid as the product of the fermentation of the kelp leaf. The acetic acid is neutralized with limestone, giving calcium acetate, potash, and iodides in the solution.

The products chart, shown in Fig. 1, will give a general idea of the operations at this plant and serve as an introduction to the more detailed description that follows. With this I think we can outline quite clearly the

FIG. 1. KELP PRODUCTS CHART

principal steps involved and the products produced in the fermentation of kelp. The kelp is harvested and brought to the plant, pumped from the tank barges into the fermentation vats where it is allowed to ferment until the kelp leaf goes into solution and a liquor is obtained which on evaporation and concentration yields, at various stages, three intermediate salts.

#### SEPARATION OF POTASSIUM CHLORIDE

The first intermediate salt, consisting of a mixture of acetate of lime and muriate of potash, is heated in regular acetone retorts, which produce acetone from the acetate, leaving as residue muriate of potash and calcium carbonate, from which the high-grade muriate is separated by leaching and subsequent crystallization. The fractionation of the crude acetone yields a certain amount of light and heavy acetone oils, in addition to the C. P. acetone.

Intermediate salt No. 2, consisting of the calcium salts of the higher fatty acids, is mixed with alcohol and sulphuric acid and the corresponding ethyl esters produced by well-known methods. These esters are easily separated by fractionation. Ethyl acetate, ethyl propionate and ethyl butyrate in commercial quantities are now on the market from this source and are finding very extensive application as solvents in the soluble-cotton industry, in the manufacture of artificial leather etc.

Intermediate salt No. 3, consisting principally of potassium iodide, is treated with chlorine and the precipitated iodine dried and resublimed.

#### GELATIN SUBSTITUTE, AMMONIA AND MEDICINAL CHEMICAL ALSO RECOVERED

The last of the final products shown on the chart is algin. This substance is at the present time being produced from the residual unfermented leaves which are screened from the liquor coming from the fermentation vats. These leaves are treated with sodium carbonate which extracts the algin in the form of a soluble sodium salt which is afterwards precipitated and purified. So far, but little progress has been made in the commercial development of the use of this algin as an article of commerce. The perfection of extraction manufacturing methods however, and the increasing cost of gelatin and vegetable gums, leads to the conclusion that this material may find a very extensive use in the future.

In addition to the foregoing valuable products, promising experiments are now in hand whereby ammonia, valeric, and caproic acids are being recovered as by-products in the fermentation of kelp. Nitrogen combined as ammonia exists to the extent of about 0.2 per cent in kelp, and is left in the liquor after fermentation of the leaf. Valeric acid as the isoform is much needed at the present time in the treatment of nervous disorders, the supply of the valerian root from which the medicinal valerates were formerly made having been almost entirely cut off.

#### KELP POTASH CANNOT COMPETE WITH UNRESTRICTED EUROPEAN SUPPLIES

Sufficient has been said I think to indicate that the kelp industry from being conceived solely as a source of fertilizer potash will eventually develop along the lines of fine chemicals with high grade muriate somewhat in the position of a by-product. It is doubtful whether the total potash production of all the kelp-harvesting concerns at the present time amounts to more than about 25 tons a day on the basis of 80 per cent muriate of potash. Of this, more than a half is of a high grade of purity about 95 per cent KCl, and is produced not by the original method involving the incineration of the kelp, but by the fermentation process already referred to.

It may be a little early yet to speak definitely of the future of the kelp industry and its future bearing on potash. Certain it is that with kelp-production factories extending all along the Pacific Coast, our domestic demands for potash cannot be met thereby. Certain it is, too, that kelp solely as a source of potash will never compete with unrestricted supplies from Europe or even with that recovered in modern cement or blast-furnace practice. The utilisation of kelp in such a way, however, as to realize on all its other possible values, some of which have been touched upon may help to render the users of high-grade potash for chemical purposes outside of the fertilizer trade, independent of foreign supplies.

#### Soluble Potash from Feldspar

B. F. Halvorsen of Christiania, Norway, patents the process of heating a mixture of finely ground feldspar, cyanamide and alkali salts to 650 deg. C. in the presence of superheated steam, whereby he gets ammonia and a good yield of soluble potash, which is refined by crystallization. (Eng. Pat. 107,012, May 30, 1917.)

## Potash as a By-Product

Southern Iron Ores and Fluxes Considered as a Domestic Source of Potash in Large Quantities—Analysis of Raw Materials—Estimated Cost of Operation—Probable Recovery and Profits

By J. S. GRASTY

Geological and Chemical Engineer, Charlottesville, Va.

IT IS, of course, a matter of general information that prior to the war Germany supplied practically all the potash salts used in the world. With but small reserve supplies of potash and the German supply entirely cut off this country has in consequence faced a serious shortage in this material so essential as a fertilizer. The best indication of this fact is that high-grade potash salts are now quoted at approximately \$350 to \$425 per ton, whereas the normal price before the war was \$35 to \$40 per ton. Further evidence on this point is given in Table I on imports of potash salts:

TABLE I—IMPORTS OF POTASH SALTS

|                       | Pounds      | Value        |
|-----------------------|-------------|--------------|
| 1912                  | 622,179,164 | \$10,692,285 |
| 1913                  | 612,514,916 | 10,805,720   |
| 1914                  | 485,818,459 | 8,743,973    |
| 1915                  | 170,550,450 | 3,765,224    |
| 1916—January to April | 3,091,250   | 379,260      |

These figures show that before the war over 600,000,000 pounds of potash salts were imported annually. Of this quantity approximately 500,000,000 pounds was in the form of chloride and 100,000,000 pounds in the form of sulphate, both of which salts are used especially for fertilizers. In 1915 the imports were less than 200,000,000 pounds, 90 per cent of which was used by the fertilizer industry.

If our normal annual consumption of potash be represented by the figures for 1912, there was in 1915 a shortage of over 450,000,000 pounds, and judging from the figures this shortage was much greater in 1916.

Table II gives the potash production of the United States for 1917:

TABLE II POTASH PRODUCTION, UNITED STATES, 1917

| Sources                                                 | Number of Producers | Available K <sub>2</sub> O, Short Tons |
|---------------------------------------------------------|---------------------|----------------------------------------|
| Mineral Sources                                         |                     |                                        |

|                                                         | 82                  | 32,366                                 |

According to the U. S. Geological Survey, the production of potash for the first six months of 1918 was between 20,000 and 25,000 tons of K<sub>2</sub>O, and it is estimated that the total production for the year will reach 60,000 tons. On the other hand, the Bureau of Soils estimates that the cement plants of this country should be able to produce more potash alone than the total estimate for 1918<sup>1</sup>. However, it should be remembered that this is only 25 per cent of our normal requirements.

<sup>1</sup>Commenting on this the editor of the *Manufacturers' Record*, Sept. 22, 1918, calls attention to the fact that the blast furnaces could probably produce 200,000 tons of K<sub>2</sub>O per year, at the same time obtaining a cleaner gas for their stoves and gas engines.

### SERIOUS SHORTAGE OF POTASH

The present condition of potash shortage is so serious that both the U. S. Geological Survey and the Department of Agriculture have directed special attention to the investigation of new sources of supply. Borings, with practically unsuccessful results, have been made in the "Red Beds" of the West and elsewhere in the endeavor to locate suitable deposits, and to determine whether or not potash salts are to be found in association with beds of common salt in sufficient quantity to be of commercial importance, but, as indicated, so far the results have not been satisfactory.

The Bureau of Soils of the Department of Agriculture has been investigating the extraction of potash from the sea weeds (kelps) of the Pacific coast. This Bureau has also investigated the various processes of the extraction of potash from feldspar etc. Important work is also being done by Dr. T. Poole Maynard of Atlanta, Ga., in

TOP BED ON RESER MOUNTAIN

investigating methods of recovery of potash from the sericite schists and slates of Georgia.

The conclusion is definitely reached that a potash industry in order to be successful must be considered strictly from the point of view of cost of production. Many enterprises which are now producing at a profit cannot expect to survive during the post-war period. In fact the only potash industries for which success is assured are those which depend upon recovering potash as a by-product, and therefore this desired end can be attained in the treatment of volatilized products of Portland cement plants and the gases of blast-furnaces by making use of the Cottrell processes of electric precipitation.

Too much emphasis cannot be placed upon the point

that potash produced in this country must be able to compete with that produced in Germany after the war. Potash recovered as a by-product should be produced at a price as low as \$15 per ton after all charges have been deducted. Also the probable tonnage and stability of the industries of which potash is a by-product must

UPPER SEAM AND PART OF LOWER SEAM AT EUMAHEE

be taken into consideration. As previously indicated, there are two extremely important sources of by-product potash in this country, namely, cement plants and iron blast-furnaces. At the present time considerable quantities of potash are being produced as a by-product of cement plants and large profits are being earned.

Very little, however, has as yet been recovered from iron blast-furnaces, although such plants offer a field for the use of processes of recovery as good as, if not better than, cement plants. Nevertheless, sufficient work has been done by Wysor<sup>2</sup> of the Bethlehem Steel Company, Porter of the Security Cement & Lime Company and others to prove that blast furnace gases do contain potash which, in many cases, can be recovered and especially so when employing iron ores which are high in potash.

Furthermore, blast-furnace gases should be cleaned of their suspended particles anyway, in order that the efficiency of the furnace may be increased. It has been found that the best way to accomplish this is by use of the Cottrell process, which in addition to cleaning the gases also recovers the potash in marketable condition. Taking into consideration the fact that it is highly advisable from an operating point of view to increase the efficiency of blast-furnaces by employing the Cottrell process to clean the gases regardless of the recovery of potash which is effected at the same time, obviously the potash so recovered is obtained at a practically negligible cost. As a matter of fact, furnace companies could afford to pay well to have their gases cleaned and give the recovered potash to the party doing the cleaning.

#### IRON BLAST-FURNACES AS A SOURCE OF POTASH

Potash recoverable from iron blast-furnaces originates in the iron ore, coke, limestone and other fluxing

agents charged into the furnace; a small amount of potash leaves the furnace in the slag and in the gases. By use of the Cottrell process the gases pass through an electric precipitator before they reach the stoves. With a given slag volume, the amount of potash carried from the furnace in the slag is more or less constant, or rather, it does not exceed a certain quantity. Therefore, of the total amount of potash charged into the furnace, obviously the greater part can be recovered from the gases. On the other hand, it is true that most iron ores, limestones and cokes do not contain much potash; consequently if large results in the matter of potash recovery are to be obtained it follows that one or more of the raw materials employed should be high in this substance.

As to the potash content of fluxing materials, either limestone or dolomite, and of coke there is offered a wide field for investigation; but the information so far available points to the conclusion that the potash content of these is in general more or less constant and fairly low as compared with the variations in potash content to be found in certain of the iron ores. After all, as goes without saying, it is the potash in the iron which is most important, although it is also obvious that

SOUTH SIDE EUMAHEE OPENING

if the fluxing materials and coke be also high in potash that is very desirable too. Furthermore, the presence of potash in the fluxing stone, coke or iron ore has an additional value because of the fact that it acts as a desulphurizer.

#### ONLY LARGE TONNAGES ARE IN ALABAMA

An investigation of the potash content of different iron-ore deposits in the United States as reported by others and as determined by the present writer forces the conclusion that the only large tonnages of potash-bearing iron ores known in this country occur in the State of Alabama. These occurrences are found in the

<sup>2</sup>"Potash as a By-product from the Blast Furnace," by R. J. Wysor, *Transactions of the American Institute of Mining Engineers*, Vol. LVI, p. 257.

eastern part of the State, in Talladega and Shelby counties, and may be assigned on a most conservative basis an aggregate of considerably over one hundred million tons of ore which is much higher in metallic content than the Clinton ores, the latter being the chief reliance of the blast-furnace industry of Alabama.

These relatively high-grade Cambrian ores occur as beds in the Weisner formation of Cambrian age in three districts, the Weewooka, Eumauhee and Columbiana. Metamorphism has altered the Weewooka and Eumauhee ores to a specular or gray hematite, while the Columbiana is bright red. The quality of these ores and their range in composition as compared with other Alabama ores are given in Table III.

TABLE III ALABAMA IRON ORES

|                             | Range in Composition,<br>Per Cent, Fe | Potash,<br>Per Cent |
|-----------------------------|---------------------------------------|---------------------|
| Weewooka and Eumauhee       | 40-52                                 | 1.50-3.00           |
| Columbiana                  | 44-46                                 | 1.00-1.25           |
| Alabama brown ores          | 40-48                                 | 0.20-0.40           |
| Alabama red or Clinton ores | 34-50                                 | 0.15-0.25           |

Ore has been mined and sold from all three of the Cambrian ore occurrences mentioned above, which, by

ORE BED AT EUMAHEE

the way, are controlled by different interests, and has been smelted with most satisfactory results—that is, in all cases where it has been properly mined free from slate. This is a point which seems worth mentioning for the reason that in one instance, at Tallasseechatee creek, the mining was conducted in such a way that the ore shipped was of rather low grade because of careless mining resulting in a large and unnecessary admixture with slate. Most of these Cambrian ore beds are, however, entirely free from slate partings. These deposits are within about forty miles of Birmingham, with other furnaces quite near at hand in the same eastern section of the State.

Referring to Table III, it will be seen that the Cambrian ores, as compared with the Clinton and brown ores of Alabama, are exceedingly high in potash. The value of their high potash content can probably best be emphasized by pointing to the fact that at the Portland

BOTTOM SEAM, NORTH SIDE EUMAHEE

cement plant of the Security Cement & Lime Company at Hagerstown, Maryland, whose deposits the writer located and whose plant has been so successfully managed by Mr. J. J. Porter, the shaley limestone used ranges in K<sub>2</sub>O from 0.75 to 1.10 per cent. The net profits obtained in recovering potash at this plant using the Cottrell electric precipitator amounted during the year 1917 to over \$200,000. Even this large profit, which is enormous considering the required outlay for equipment and operation, will probably be exceeded by a blast-furnace treating a corresponding quantity of material; that is, assuming the blast-furnace runs on these high-potash ores in sufficient quantity and at the same time employs the Cottrell process for catching the potash. It will be seen how closely the comparison holds between a 3000-barrel cement plant, the capacity of the plant at Security, and a 200-ton blast-furnace when it is stated that both handle approximately the same quantity of raw material.

Table IV brings out the potash value to be recovered using Cambrian ores as compared with Clinton ores of different grades:

TABLE IV—VALUE OF RECOVERABLE POTASH FROM CAMBRIAN ORES

| Recovery, per cent. | 40        | 45        | 50        | 55        | 60        |
|---------------------|-----------|-----------|-----------|-----------|-----------|
| Value               | \$467,247 | \$525,643 | \$584,058 | \$642,464 | \$700,870 |
| Recovery, per cent. | 65        | 70        | 75        | 80        |           |
| Value               | \$759,276 | \$817,681 | \$876,087 | \$934,494 |           |

Mr. Charles Catlett of the War Industries Board states<sup>3</sup> that the average analysis of a number of samples of these specular hematites shows a potash content of 2.08 per cent, and he calls attention to the fact that this is over seven times the potash contained in the mixture used by Mr. Wyser at the Bethlehem Steel Company's plant.

Table V showing the cost of producing pig iron, depending upon the kind of ore used, and the estimated results in potash recovery and profits therefrom by the erection of a Cottrell electric precipitator at a 200-ton

<sup>3</sup>Manufacturers' Record, March 29, 1917.

iron blast-furnace, was prepared in collaboration with Mr. Linn Bradley, Chief Engineer of the Research Corporation. In this connection it should be stated that the Research Corporation of New York City owns the patents covering the Cottrell process as applied to the recovery of potash from iron blast-furnaces and for other uses except as applied to Portland cement plants.

WEST SIDE MAIN CUT, TALLASSAHATCHEE

which rights are owned by the Western Precipitation Company. Mr. Bradley having had charge of installations of Cottrell electric precipitators for the Research Corporation since its organization, and having given his attention to the recovery of volatilized products of various sorts by use of these processes, any statement from him on these subjects is authoritative.

TABLE V—ESTIMATED RESULTS OF COTTRELL ELECTRIC PRECIPITATOR INSTALLED AT A 200-TON IRON BLAST-FURNACE

| Items                                                    | Coke      | Limestone | Dolomite  | No. 1 Camb. Ore | No. 2 Red. Ore | No. 3 Brown Ore |
|----------------------------------------------------------|-----------|-----------|-----------|-----------------|----------------|-----------------|
| Material cost, long ton...                               | \$1 00    | \$1 00    | \$5 00    | \$2 00          | \$3 50         |                 |

| Furnace capacity in tons iron output per day...          | 230       |           | 180       | 220             |                |                 |
| Total material cost per day                              | \$4 993   |           | \$4 381   | \$4 739         |                |                 |
| Average value per ton iron produced                      | \$33 00   |           | \$31 50   | \$33 00         |                |                 |
| Gross value of output of iron per day                    | \$7,590   |           | \$5,670   | \$7,260         |                |                 |
| Gross profit on iron output per day                      | \$2,597   |           | \$1,289   | \$2,521         |                |                 |
| (Labor, overhead, etc., not considered)                  |           |           |           |                 |                |                 |
| Gross profit on iron output per year, as above           | \$908,950 |           | \$451,150 | \$882,350       |                |                 |
| Total potash content of burden per ton of iron, pounds   | 99 50     |           | 34 43     | 33 97           |                |                 |
| Deduct for losses in slag and elsewhere                  | 20 96     |           | 31 38     | 23 46           |                |                 |
| Potash remaining, unknown portion, collectible, pounds   | 78 54     |           | 3 15      | 10 51           |                |                 |
| Gross value potash at present price \$5 per unit         |           |           |           |                 |                |                 |
| 350 days taken as one year's operation:                  |           |           |           |                 |                |                 |
| Equal to 25 per cent water-soluble                       | \$395,154 |           | \$12,403  | \$50,579        |                |                 |
| Equal to 35 per cent water-soluble                       | \$53,216  |           | 17,364    | 70,811          |                |                 |
| Equal to 40 per cent water-soluble                       | \$32,247  |           | 19,844    | 80,927          |                |                 |
| Estimated net value potash per annum—present 25 per cent | 165,000   |           | 165,000   | 165,000         |                |                 |
| Estimated net value potash per annum—present 35 per cent | 230,154   |           |           |                 |                |                 |
| Estimated water-soluble percentage—35 per cent           | 388,216   |           |           |                 |                |                 |
| Estimated water-soluble percentage—40 per cent           | 467,247   |           |           |                 |                |                 |

It is Mr. Bradley's opinion, backed by data which he has assembled, that a 40 per cent recovery of water-

soluble material may be confidently relied upon as a minimum, though he admits that in practice much larger yields are attained, since, for instance, Mr. Catlett, who has served as chemical advisor of the Security Cement & Lime Company, considers an 85 per cent recovery conservative. Mr. Catlett also estimates that under present conditions potash recovered at a blast-furnace using the Alabama Cambrian iron ores would be worth from \$12 to \$15 per ton of iron produced, which means in potash values alone for a 200-ton furnace \$2400 to \$3000 per day.

As is well known, it is the trade custom to sell potash on a basis of the units of pure potash, a unit being 20 pounds. The present market price for agricultural potash is around \$5 per unit as against 60 and 70c. during the pre-war period. As to this matter of prices, it is the opinion of those best acquainted with the industry that the price of potash will remain relatively high for a number of years after the war.

#### ESTIMATED COSTS AND RECOVERIES

The cost of collecting potash by use of the Cottrell process is estimated in Table VI.

TABLE VI—COST OF COLLECTING POTASH

|                                                                            | Per Unit K <sub>2</sub> O |
|----------------------------------------------------------------------------|---------------------------|
| Collection, including labor, power, repairs and laboratory                 | \$0 14                    |
| Packing and shipping                                                       | 08                        |
| Total operating cost, exclusive of depreciation, royalty and salt addition | \$0 22                    |

The cost of the salt addition—about 25c. per unit of potash—is not a necessary element, and can be omitted

EAST SIDE MAIN CUT, TALLASSAHATCHEE

whenever price conditions are such as to give an unsatisfactory margin of profit.

The following figures<sup>a</sup> taken in connection with the calculated recovery will give a basis for estimating cost in any particular case:

Labor required for operation—1 foreman, who can also supervise packing and loading, and 1 or 2 operators per shift—about \$12 per day.

<sup>a</sup>Manufacturers' Record, March 29, 1917.

All costs given in this paper are recent and are considered correct, but to be conservative from 10 to 15 per cent. might be added to the total.

All figures on operating costs here given have been supplied by Mr. Porter and are based on actual practice at the 3000-bbl. Portland cement plant of the Security Cement & Lime Co. Inasmuch as a 200-ton iron blast-furnace, according to Southern furnace practice, handles approximately the same quantity of raw material as a 3000-bbl. cement plant, the cost of operation of a Cottrell electric precipitator should be approximately the same in both instances.

Laboratory—1 additional chemist,  
say \$4 per day.

Power—1300 kw.-hr. per day for 3000-bbl. plant based  
on dry collection plant—about \$12 per day.

Operating costs and profits would be about as in Table  
VII.

TABLE VII—OPERATING COST

|                                                                   | Per Bbl. Clinker         |                        |
|-------------------------------------------------------------------|--------------------------|------------------------|
| Labor                                                             | \$27 00 per day—\$0 0090 |                        |
| Power                                                             | 25 00 per day— 0083      |                        |
| Repairs                                                           | 8 00 per day— 0027       |                        |
| Laboratory                                                        | 120 00 per mo.— 0014     |                        |

For the benefit of those who wish to estimate the probable recovery of potash at a given plant, the potash content of whose raw materials has been determined by analysis, and the percentage lost in the slag having

ORE BED ON HEGCPACK MOUNTAIN

also been determined, the method of calculation here indicated, which is adapted from that used by Porter for cement, is submitted:

Let *A* equal per cent of potash in furnace burden, i.e., average of  $K_2O$  in ore, stone and coke.

Let *B* equal per cent potash in slag. This ranges from 0.0017 to 0.0065 per cent, average being 0.0039 per cent.

Let *C* equal liberation of potash. This equals:  
9500*A* - 3800*B*

9500*A*

Let *F* equal lb. potash recombined in slag. This compares with potash combined with clinker in manufacturing cement as follows; the range in per cent in cement is from 0.002 to 0.0039, and in slag from 0.0017 to 0.0065, the average in the latter being 0.0039.

Let *P* equal per cent potash precipitated in treaters. This should be 80 to 90 per cent of the total entering. Assume 9500 lb. burden actually used to produce one ton pig iron, and yielding 3800 lb. in slag.

Pounds potash entering furnace per ton pig iron equals 9500*A*.

Pounds water soluble potash entering precipitators per ton pig iron equals 9500*AC* - *F*.

Pounds water soluble potash collected in treaters per ton pig iron produced equals (9500*AC* - *F*) × *P*.

If the average furnace burden be, say, one per cent potash and the loss in the slag 0.0039 per cent., or about

14 lb. per ton of pig iron, then the potash liberation will be about 85 per cent of the total present, and 3.29 units of potash; i.e., 65.43 lb. of potash per ton of pig iron will be produced. The value of a unit of potash is now over \$5, being in fact nearer \$6; but taking it at \$5 per unit, the total value of potash produced at a 200-ton furnace will amount to approximately \$3000 per day. This, however, is assuming that the Cottrell process will effect a recovery such as is experienced in practice, varying from 80 to 90 per cent. But assuming Bradley's minimum of 40 per cent water-soluble recovery, then the total net profit per annum for a precipitator installed at a 200-ton blast furnace—after deducting liberally to cover cost of operation, complete amortization the first year, interest on investment etc., and considering only the positively water-soluble material, i.e. 40 per cent—should be approximately \$500,000, a result which is most amazing, but which reflects the present scarcity of potash as expressed by the prices now obtaining.

#### LARGE PRODUCTION NECESSARY TO PREVENT FUTURE GERMAN MONOPOLY

However, whether maximum profits be attained or not, it should be borne in mind that money so invested would be largely instrumental in giving us complete independence of Germany as a source of potash. Furthermore, no one knows how long the war is going to last, but every one knows that potash is an important plant food. This being the case, and with food and other plant products playing so large a part in winning the war, it is undoubtedly a patriotic duty to push the recovery of potash as a by-product energetically and to the limit. Raw materials high in potash are known, they are well located and available in large quantities; the Cottrell process has been thoroughly worked out, and the recovery of potash by its use, having already passed through the early experimental stages, has been fully demonstrated to yield satisfactory results. It is also highly important to establish the potash industry on a profitable basis in the United States in the near future, so that Germany cannot claim her former monopoly of potash when peace is restored. In view, therefore, of these pertinent facts, those of us who fail to take active steps now in this regard are slackers indeed.

#### The Sylvine Deposit in Alsace

A potassium chloride brine containing very little magnesium, the latter having been leached out during formation, was discovered near Mulhausen in Alsace in 1904, when deep borings were being drilled in testing out this locality for petroleum. In 1909 the first mining shaft was sunk and in the following year, 37,000 tons of potash salts were produced. The industry grew very rapidly and in four years, twelve mines were being operated. The Prussian Potash Syndicate decided to allot to this territory one twenty-fifth of the entire German production of ten million tons, so as to curtail the development of new mines. The extent of the deposit is not definitely established, although about seven square miles of sylvine from six to thirty feet thick, containing one billion cubic yards and one and a half billion tons of crude salts of 22 per cent  $K_2O$  analysis has been located.

# A Wet Process for Extracting Potash from Cement Dust

A Detailed Description of a Humidifying Process for the Precipitation of Potash-Bearing Dust from Cement Kilns, Together with Drawings of a Unique Condenser-Evaporator Set Made of Reinforced Concrete

By J. G. DEAN

Chemical Engineer, Southwestern Portland Cement Co.

ONE TON of potassium sulphate per day is being made at the Victorville, Cal., plant of the Southwestern Portland Cement Co. This is but one feature of a very interesting plant, the details of whose design and operation are largely due to their mechanical engineer, Mr. L. D. Gilbert. The potash plant now operating is hardly more than an experimental installation, and was installed at a cost of approximately \$25,000. However, the modest plant shown in Fig. 1, is rapidly paying for itself, and at the same time is yielding information which is being utilized in the design of a more balanced installation to make a better recovery of water soluble potash on the entire kiln effluent.

## GENERAL FEATURES OF THE CEMENT PLANT

It may be interesting to preface the discussion of the potash recovery system by a brief note on the design of the cement plant, which itself is an example of modern practice, being built in 1915 and 1916, begin-

Chalmers preliminarator followed by a No. 18 F. L. Schmidt tube mill. The latter delivers a slurry containing 35 to 37½ per cent of water, the solids in suspension running 90 to 94 per cent through 200 mesh.

This slurry is then pumped into one of a series of eight round storage tanks, 16 ft. in diameter and 36 ft. high, containing 225 tons of solids—sufficient for 18 hour's burning. After this tank has been filled, it is agitated by compressed air for a period of 2 hours, sampled and analysed for CaO and total loss on ignition. Any adjustment necessary for correct chemical composition is then made by drawing proportional volumes from two or more of these storage tanks, delivering the mixture to a supply tank, which is one of the series shown to the right of the kiln in Fig. 2 exactly similar to the storage tank. When this is filled it is air-agitated, check-analysed, and is then ready for delivery into the kiln.

FIG. 1.—EXPERIMENTAL POTASH INSTALLATION

ning operation in September, 1916. The rock, which is a shattered limestone, impregnated with seams of clay, is steam shoveled at the quarry and delivered by standard gage railroad five miles long to the coarse crushing department. Here the rock is broken by a 36 by 60 Allis-Chalmers Fairmont roll crusher, and then delivered to a No. 7 Jumbo Williams mill, which discharges material at about ½-inch size. The discharge from the Fairmont roll crusher may be screened when desired, and the fine screenings washed to remove some clayey material, since the natural product is somewhat deficient in lime. The crushed rock is then elevated to storage bins of 450 tons capacity.

The fine grinding department operates two ten-hour shifts, the rock being wet ground in an 8-ft. Allis-

This kiln, (Fig. 2), is 9 ft. in diameter and 200 ft. long, jointed in the middle, oil burning, and capable of producing 1000 barrels of clinker in 24 hours. The latter is dug from the discharge pile by a clam shell and spread in longitudinal ridges by a locomotive crane running on a track through the middle of a concrete storage-bin, 318 ft. long and 66 ft. wide. The same crane reclaims the material for the finish department by digging across the bin at right angles to the bedding, this method of handling insuring a very well mixed clinker. Grinding is done in an Allis-Chalmers 7-ft. by 22-ft. Compeb mill, from which the cement is discharged and stored awaiting sacking and shipment in a series of bins, 27.5 ft. in diameter and 65 ft. high, each having a capacity of 10,000 barrels.

## KILN DUST

As shown in Fig. 2, the kiln is mounted directly above a concrete dust chamber 12 ft. wide, 14 ft. high and 200 ft. long. Since the wet process was to be used, no great amount of dust was expected, so the chamber was made with a flat bottom and no mechanical device installed to handle the settlement. However, it was found that ap-

use the Cottrell process, and so we cast about for an alternative and hit upon the present scheme.

## PRECIPITATION BY WATER AND WATER VAPOR

Briefly, we planned on spraying the hot gases with sufficient water to wash out the particles in suspension, filtering the spray water from its insoluble sludge, and

FIG. 2.—GENERAL LAYOUT OF KILN BUILDING

proximately 3 per cent of the solid charged as slurry was recovered in the dust chamber—that is to say, about 270 tons of finest dust had to be shoveled out every month. As shown by the curve, Fig. 3, analysis of this material returned 1.4 per cent water-soluble  $K_2O$  at the kiln end, rising to 2.5 per cent at the stack end. Fig. 3 also shows that the fineness increased progressively, as would be expected; near the stack practically all of the material would pass a 200-mesh screen. The quantity line is approximate, indicating that there is a much greater amount of the low-grade, coarser material than of the finest, higher-potash dust.

While the dust chamber potash was evidently a bird in hand, an economical method of catching the unknown quantities of richest and finest dust emitted from the

evaporating the filtrate. For the latter operation every consideration pointed to the desirability of using the flue gases as a source of heat. Whether to build the evaporator ahead of the spray chamber or beyond it was given careful consideration: in case hot furnace gases above 100 deg. C. were used an evaporator at atmospheric pressure could be utilized, thus simplifying and lightening the evaporator construction and obviating the need of vacuum pump and condensers. However, if these gases were sprayed, they would have required large radiating surfaces or else a prodigious amount of vaporized water would have been lost in the hot saturated stack gases. Furthermore it was early found that the largest excess of water dripping through dusty gases failed to wet and precipitate satisfactory amounts of the solids rich in potassium. This is in line with the well-known difficulty—almost amounting to an impossibility—of satisfactorily and completely wetting finely divided particles such as flowered sulphur and many other condensates. However, if saturated dusty gases are cooled so that the water vapor contained will condense, the nascent globules of mist form about the dust particles as nuclei. Now if the resulting fog can coalesce and be collected in some way the result will be a dust-free gas saturated with vapor at the temperature of escape, and a sludge containing soluble salts in solution and insoluble particles in suspension.

Evidently, then, it was not only necessary to thoroughly humidify the hot gases, but even more necessary to cool the gases to the least possible temperature before their discharge. The radiating heat from these cooling gases could naturally be utilized to evaporate the considerable quantities of weak solutions produced—every pound of water condensed would give up sufficient heat to evaporate another pound of water.

From these and like considerations a condenser-evaporator shown in cross-section in Fig. 1 and discussed in detail later, was placed after the spray chamber. In operation the water which condenses inside the tubes evaporates the same amount outside the tubes; the cool-

FIG. 3.—RECOVERY OF  $K_2O$  IN DUST CHAMBER

stack urgently demanded attention. A somewhat standardized and familiar solution of this problem is the use of the Cottrell system of electrostatic precipitation. Many of these installations, however, while catching all of the coarser dust, pass a considerable percentage of impalpable material, which unfortunately is most desirable, since it has the largest potassium content of any fraction. Again, owing to certain business considerations we were unable to obtain a satisfactory license to

ing furnace gases give up heat to evaporate excess additions, and the gases escape at a low temperature with their waste heat largely abstracted and utilized.

### CHEMISTRY OF PROCESS

The potassium and sodium in the feldspar and other minerals contained in the cement rock mixture are volatilized as oxides to a certain extent by the intense heat in the clinkering zone, and probably react with sulphuric acid anhydride to form their sulphates. The sulphur in the fuel oxidizes as follows:

After these reactions take place near the focus, if the sulphates pass on into a reducing atmosphere sulphides will be formed, according to the typical reaction:

Thiosulphates and carbonates are also formed in the hot, humid gases according to one or more of the following reactions:

On reaching the spray chamber, then, the gases bear particles of fume consisting in part of potassium and sodium sulphides, sulphates, and thiosulphates, together with some complex polysulphides. The water which washes these particles out of the gas also absorbs carbon dioxide. Some bicarbonates will form in the condensate in this manner:

These bicarbonates rapidly oxidize any remaining sulphides as follows:

The hydrogen sulphide rapidly hydrolyzes to water and sulphur, which latter reacts with any sulphite, which may rarely be present

A considerable quantity of this sulphur also condenses on the sides of the stack through which the spent, cool kiln gases eventually escape.

Somewhat in the above manner the mixed spray chamber sludge and condensate contains in solution principally the following ions:

Potassium sulphate can readily be separated from sodium thiosulphate; the former crystallizes from hot solutions, while the latter comes down on cooling; therefore it is desirable to remove the  $CO_3^{==}$  and furnish  $SO_3^{==}$  in its stead. This is done at present by drawing the solutions through a bed of gypsum which effects the interchange as follows:

the calcium carbonate remaining behind as an insoluble. Calcium sulphate must be used with circumspection here, however, since gypsum is soluble in thiosulphate, and the whole evaporating system may become overloaded with gypsum, effectually interrupting operations. This may readily be prevented by making sure that a little  $CO_3^{==}$  remains in the solution after gypsum treatment. The test is easily made for the carbonate ion with normal HCl using methyl orange as an indicator. By this titration to a faint pink color the sulphur of the

thiosulphate will not separate out. The solution is then titrated with 0.1 N iodine for the thiosulphation. An increased acidity rarely occurs by the oxidation of the iodine by small amounts of sulphite present.

The liquor now contains  $Na^+$ ,  $K^+$ ,  $SO_3^{==}$ , and  $SO_4^{==}$ . Since there is not enough sulphate anion to unite with all of the potassium present, a part of the potassium would crystallize as thiosulphate if the solution were evaporated. As an actual fact, in the presence of sodium ions the double salt  $K_2S_2O_3 \cdot Na_2S_2O_3 \cdot \frac{1}{2}$  to  $1\frac{1}{2}H_2O$  is formed, which together with  $K_2SO_4$  represents the salt collected from an evaporation in our crystallizing evaporator. Since the amount of sodium present in the weak sodium ions the double salt  $K_2S_2O_3 \cdot Na_2S_2O_3 \cdot \frac{1}{2}$  to  $1\frac{1}{2}H_2O$  vents its concentration. Whenever the  $Na^+$  reaches a saturation point, a small drop in temperature will freeze the crystallizer solid with the sudden precipitation of  $Na_2S_2O_3 \cdot 5H_2O$ . In actual practice the salts as they come from the crystallizer-evaporator are dried and heated to remove a part of the sulphur of the thiosul-

FIG. 4—PROGRESSIVE COMPOSITION CHART OF WET PROCESS KILN

phates. This gives a product of about 90 per cent  $K_2SO_4$ , which is entirely acceptable to our customers.

If it is desirable to prevent the formation of the double thiosulphates, enough  $Na_2SO_4$  may be added to the solutions to furnish the necessary amount of  $SO_4^{==}$  for the  $K^+$  present in excess. This salt also furnishes the requisite amount of  $Na^+$  for the  $SO_3^{==}$ . Pure potassium sulphate will then crystallize from boiling solutions up to the point of saturation of the sodium salt. Now if these hot solutions are drained into a crystallizing tank and allowed to cool,  $Na_2S_2O_3 \cdot 5H_2O$  will crystallize, while the potassium sulphate remaining in the mother liquor can be returned to the primary evaporator.

### BURNING CONDITIONS IN THE KILN

As was stated at the beginning of the discussion of the chemistry of the process, in order to produce the thiosulphates and carbonates in the final liquors it is necessary to have a slightly reducing condition in the kiln. This has been brought about, apparently, by the improper atomization of the oil fuel. While this condition has operated largely in favor of easy manipulation of the potash liquors and the final purification of the potash salts it has not helped in volatilizing the potash from the raw materials in the kiln itself. So far it has

been impossible to volatilize more than about 45 per cent of the potash content, as is shown by the composition chart given in Fig. 4. If the burning conditions could be changed so as to produce the short, intense flame necessary for the most efficient production of cement clinker with the minimum amount of fuel, it

detail in Fig. 5, which is merely a section of the flue about 30 ft. long equipped with fifty Demeral spray nozzles in top and sides. The three tanks in the V-shaped bottom are provided with valves in the bottom, the first of the tanks receiving the condensate from the condenser-evaporator set, as noted later. The collected

FIG. 5.—LONGITUDINAL SECTION OF SPRAY CHAMBER

would undoubtedly increase the volatilization of the potash considerably at the same time. To do this would destroy the reducing atmosphere necessary for the formation of the thiosulphates and carbonates, and would make the handling of the liquors more difficult and the separation of the potassium and sodium salts practically impossible. However, a method is now under consideration that will make it possible to take advantage of both conditions, giving a maximum cement production and potash volatilization together with our present ease in handling the liquors and purifying the final salts.

The addition of salt ( $\text{NaCl}$ ) to the kiln feed would undoubtedly increase the volatilization of the potash. On the other hand, this would decrease the purity of the final product. The introduction of chlorides is not altogether desirable for other reasons as well. Fluorspar added to the raw material would achieve the same result without the addition of new salts to the final product. In an installation described under "a permanent installation," where all the insoluble dust is returned to the kiln, the  $\text{CaF}_2$  would be reclaimed and used over and over again.

The raw materials as they come from the quarry are somewhat deficient in  $\text{SiO}_2$ . This is corrected by adding a small amount of granitic rock found along the right of way. This material analyzes about 5 per cent  $\text{K}_2\text{O}$ , and its use increases the potash content of the raw materials entering the kiln from about 1 per cent to an average of 1.2 per cent. If we had a pure limestone to use it would be possible to increase the potash content by the addition of the feldspar available to more than 2 per cent.

#### OPERATION OF EXPERIMENTAL PLANT

The drawing, Fig. 1, indicates the main features of the experimental plant. An opening was cut in the end of the dust chamber underneath the kiln and a concrete dust flue built under the firing floor. Just outside the kiln building is located the spray chamber shown in

sludge is drawn at regular intervals into a trough leading to an elevator driven from the fan shaft and from which it is delivered to a small Oliver filter. The filtrate, together with the overflow from the condensate-receivers goes to a concrete storage tank 10 ft. by 10 ft. by 6 ft. deep, holding 4500 gallons.

In passing it may be noted that the atmosphere above the settling tanks as well as the sludge water is strongly charged with ammonia. It is probable that this ammonia comes from the combined nitrogen in the fuel, and its collection is one of the problems for future consideration.

The gases leaving the kiln average 700 deg. F. in temperature. They seldom contain oxygen, and therefore indicate no excess air; in spite of the known reducing condition in the kiln atmosphere they seldom contain carbon monoxide. Table I gives the computation of the kiln-stack conditions, allowing for no infiltration of air, from which it may be computed that at standard conditions of temperature and pressure the gases amount to 15,000 cubic feet per minute and analyze approximately:

|                      | Per Cent |
|----------------------|----------|
| $\text{CO}_2$        | 15.8     |
| $\text{N}_2$         | 46.7     |
| $\text{H}_2\text{O}$ | 36.5     |

On passing through the dust chamber the temperature drops to about 450 deg. F., due to radiation and dilution with the outside air which is drawn through the cracks and expansion joints in the concrete walls. This dilution will average under general conditions approximately 50 per cent.

A considerable excess of water is used in the spray chamber, about 50 gallons per minute being drawn off in addition to that vaporized by the hot gases. These finally enter the condenser-evaporator tubes at 250 deg. F., 79.5 pounds of water having been evaporated to cool the gases to this temperature while passing through the spray chamber.

On entering the tubes of the condenser its volume at standard conditions of temperature and pressure is

24,000 cu.ft. per minute, and its composition may be figured to be:

|                  | Per Cent |
|------------------|----------|
| O <sub>2</sub>   | 6.4      |
| CO <sub>2</sub>  | 9.8      |
| N <sub>2</sub>   | 54.4     |
| H <sub>2</sub> O | 29.3     |

During the passage through the condenser tubes the temperature of the wet gases further falls to 140 deg. F., and is discharged holding only 6.37 pounds of true water vapor per thousand cubic feet of gas, plus some entrapped mist which failed to collect in the condenser tubes. This will amount to between 60 and 75 pounds per minute. The evaporator itself operates at 24 inches vacuum (3 inches absolute pressure at the elevation of Victorville) and a temperature of 115 deg. F.

During the passage through the condenser tubes the gasses have thus radiated the following amounts of heat per minute in cooling from 250 to 140 deg. F.:

|                                                                          | B.t.u.                  | B.t.u.  |
|--------------------------------------------------------------------------|-------------------------|---------|
| O <sub>2</sub> .....                                                     | 1,560 cu.ft. at 2.28 =  | 3,556   |
| N <sub>2</sub> .....                                                     | 13,144 cu.ft. at 2.28 = | 28,968  |
| CO <sub>2</sub> .....                                                    | 2,380 cu.ft. at 2.87 =  | 6,830   |
| H <sub>2</sub> O .359.5 pounds entering at 250 deg. F.<br>contains ..... | 416,021                 |         |
| 114.0 pounds leaving at 140 deg. F.<br>contains .....                    | 127,861                 |         |
| 245.5 pounds condenser losses.....                                       |                         | 288,160 |
| Total radiation in condenser..                                           |                         | 327,514 |

Supposing that 90 per cent of this heat is transferred through the condenser tubes and is utilized in evaporating water at 3 inches absolute and 115 deg. F., 283 pounds of water would be evaporated per minute. (Since one pound of water at 100 deg. F., the temperature of the liquor entering the evaporator, contains 68 B.t.u. and the total heat of water vapor at 115 deg. F., the temperature of evaporation, is 110.2 B.t.u., the difference of 1042.2 B.t.u. is the heat absorbed in evaporating one pound of water. Therefore,  $0.90 \times 327,514 \div 1042.2 = 283$  pounds of water evaporated per minute.)

The water balance for one minute may then be tabulated thus:

|                                                     | Pounds |
|-----------------------------------------------------|--------|
| Vapor from slurry and combustion in cement kiln.... | 280.0  |
| Vapor from spray coolers.....                       | 79.5   |
| Total water entering condensers.....                | 359.5  |
| Less vapor uncondensed.....                         | 114    |
| escaping mist.....                                  | 70     |
|                                                     | 184.0  |
| Balance condensed .....                             | 175.5  |
| Amount evaporated .....                             | 283.0  |
| Excess over condensate.....                         | 107.5  |

This excess is made up by spray-tank sludge, wash water and reagent solutions.

It is apparent that considerable latitude for adjustment is possible in the evaporation system. For instance, if the quantity of weak liquor in the storage tank builds up, it is only necessary to reduce the amount of water entering the spray chamber. This not only produces a smaller amount of sludge water to be evaporated, but passes a hotter gas, which, while it transfers very nearly the same amount of heat through the tubes of the condenser-evaporator in cooling to the proper temperature —140 deg. F.—forms less condensate which must later be evaporated. Or the condensate may be put back

with the spray water, since the water line supplying the spray chamber is connected to the liquor-storage, cooling pond and the regular plant water supply.

#### CONDENSER-EVAPORATOR

As is shown in the drawing, Fig. 6, the condenser-evaporator is of reinforced concrete construction. The flue sheets are  $\frac{3}{4}$  in. steel plates tied to the reinforcing steel at the edges. The concrete walls are heavily reinforced to withstand the outer pressure due to vacuum as well as the inner pressure of the liquor. A few settlement cracks have occurred, but these have been easily sealed by an application of asphaltic paint to the

outside of the walls. A vacuum of 23 to 24 in. at an elevation of 2700 ft. is fairly good evidence that the materials of construction are not lacking in many essentials. The necessary clean-out doors have been placed at each pass, as shown in the detailed drawing. The accumulated sludge is easily removed at intervals of 24 hours with a swab provided with a water spray. Clean-

ing requires about an hour and is easily done, since there are no hard incrustations to remove.

The set contains 1052 tubes,  $3\frac{1}{2}$  in. in diameter and 14 ft. long, divided into three passes, as shown. The only tubes that could be had at the time of building were of very poor quality, which necessitated patching and welding a great many seams. However, we have not experienced the least trouble since placing them in the flue sheets.

In order to provide the extra surface for collecting the condensed water, the tubes are divided into three passes. That portion of the condensate which does not coalesce in the tubes is carried out as entrained mist, as has already been mentioned during the discussion of the water balance of the system. The collected condensate is drained through a water seal to the first

FIG. 6.—DETAILS OF CONDENSER-EVAPORATOR

settling tank provided in the spray chamber (Fig. 5). The combined liquors after passing through the three settling tanks run by gravity to the 4500-gallon tank mentioned in the discussion of the spray chamber, and will average from 2 to 2.5 per cent potassium sulphate.

The liquors surrounding the tubes on the inside of the condenser-evaporator are vaporized by means of the condensation taking place within the tubes. In order to provide the necessary temperature gradient, a vacuum is maintained in the evaporator of from 23 to 24 in. mercury, or an absolute pressure of from 3 to 4 in. Consequently the liquor in the evaporator is vaporized at 115 to 120 deg. F., while condensation on the other side of the tubes is taking place at approximately 208 deg. F. Obviously, the greater vacuum inside the evaporator the greater the temperature drop across the tube, and the lower the temperature of the exit gases.

Vacuum is provided by means of a condenser of the rotating jet type, known as the "Rees-Roturbo" condenser, supplied by the Manistee Iron Works, of Manistee, Mich. This condenser is connected with the evaporator by welded pipe as shown in Fig. 1. The condensing water and condensates flow by gravity to a cooling pond, 50 ft. by 200 ft. by 3.5 ft. deep, where it is cooled by suitable sprays. Cooled water is returned to a well shown directly under the condenser (Fig. 1) and is drawn back to the rotating jets for re-use. The

necessary screens are provided to prevent refuse from entering the machinery.

The Roturbo condenser is direct connected to a 75-hp. induction motor, which also drives the necessary pumps, sludge elevator, and an Oliver continuous filter with its vacuum pump.

The draft fan is belt-driven by a 30-hp. induction motor. The stack between the kilns is provided with a water-sealed damper, while the flue leading to the fan is provided with a swinging damper. Whenever, it is desired to close down the potash treater, the damper in the stack is raised and that in the flue closed so that the operation of the kiln is not interrupted.

#### SAND FILTER AND GYPSUM TREATER

Condensate and spray chamber overflow collected in the 4500-gallon tank contains mud and unconsumed carbon in suspension besides the substances mentioned and discussed under "The Chemistry of the Process." The solids are removed by a sand filter placed in the bottom of one of the gypsum bins at the end of the clinker storage. Whenever the liquors need a treatment for the removal of the  $\text{CO}_3^{=}$  and the addition of the  $\text{SO}_4^{=}$  ions, crushed gypsum rock is spread over this sand filter and the sludge and precipitated calcium carbonate are removed simultaneously.

A filtered liquor is now ready for the condenser-evaporator and is run by gravity to one of the crystallizing tanks shown at the right of Fig. 1. These tanks are 15 ft. by 50 ft. by 4 ft. deep, and hold 25,000 gallons. They were originally built for crystallizing the salts by cooling the saturated brines, but since installing the crystallizing evaporator shown in outline in Fig. 1, and described later, these tanks are being used for storage purposes. As necessary, the weak liquor is pumped into the cylindrical tanks alongside the condenser-evaporator (Fig. 6) and from there flows into the evaporator as needed.

#### KILN DUST CHAMBER

Fine material accumulating in the dust chamber beneath the kiln is at present drawn out through side doors and conveyed to a mixing chamber near the slurry tanks at the upper end of the kiln. This dust is made into a thin slurry with water, and when thoroughly agitated is elevated to an Oliver filter. The filtrate averages about 2 per cent potassium sulphate, and is pumped to the sand filter.

The original intention was to return the filter cake to the slurry tanks, but for some reason not yet determined a very little of this cake will thicken a whole tank of slurry so that it will not run through the outlet pipes provided at the bottom of the tanks. Even if the cake is put into the bottom boot of the elevator, the slurry in the buckets will become so thick and pasty that it will not drop out at the top. However, if the cake is directly introduced into the kiln at about the same rate as it is collected it gives very little trouble, while if too much is fed into the kiln it becomes very dusty and hard to regulate.

A crystallizing evaporator was an after consideration. Originally the liquors were concentrated in the evaporator-condenser to 24 to 26 deg. Bé. and then drained into the crystallizing tanks to cool and crystallize. After

a certain number of days the mother liquor was returned to the evaporator.

This method was too slow and cumbersome. The salts were very wet, the drying was tedious, and as the alkalinity increased in the liquor the amount of solids

drop out of solution they settle into the lower or crystallizing compartment. Every 24 hours the gate valve separating the two is closed and the liquor pumped from the lower to the upper compartment. After the salts are thoroughly drained the door is

FIG. 7.—DIAGRAMMATIC LAYOUT, COMBINED INSTALLATION, POTASH RECOVERY PLANT

held in solution increased very rapidly. Thus the difference of solubility in cold and hot solutions became so small that we abandoned this method and installed a crystallizing evaporator.

The plan of using the crystallizing evaporator as a second effect to the condenser evaporator was considered. The hot gases in the dust chamber were also a possible source of heat, but it was finally decided to use steam from the boiler in the kiln-room. Of course this is not an economical way of performing the operation, but it was considered best at the time.

The evaporator was designed by Mr. Gilbert, and built at one of the sheet metal shops in Los Angeles. There is nothing about it of unusual design, it being simply a steel tank with a conical bottom closed by a

opened, the salts removed, dried and are then ready for shipment.

#### PERMANENT INSTALLATION

Since the experimental installation is something of a pioneer in this method of potash recovery, it would be nothing strange if some troubles had developed that had not been fully anticipated. These different situations have been met as they occurred, and by their actual or evident solution a design of a permanent plant has been evolved. Fig. 7 is a diagrammatic drawing showing most of the essential changes that would be incorporated.

The dust chamber would be designed so as to be easily cleaned by means of screw conveyors running underneath. It should be mentioned here that there is no particular necessity of having a dust chamber as large as the one here shown. The chamber at present under the kiln was constructed at the time of building the cement plant, while of course the spray chamber was added later. With a shorter dust chamber it would be possible to do all the leaching and filtering at the potash recovery plant and to return the combined filter cake to the kiln.

CHART I.—FLOW SHEETS OF PRESENT AND PROPOSED PERMANENT INSTALLATIONS

10-in. gate valve which in turn is bolted to a closed tank beneath, as shown in outline in Fig. 1. This lower chamber is provided with a clean-out door, grate and drain-pipe. The steam basket is built of sheet metal, with ten 3-in. vertical flues. The basket is placed in the upper part of the conical portion of the upper tank with the necessary steam pipe and drain leading through the sides of the evaporator, and the condensed water is returned to the boiler through a trap.

At present the liquors are concentrated in the condenser-evaporator to from 15 to 18 deg. Bé. and then pumped into the crystallizing evaporator. As the salts

for considerable expansion of the gases and for deposition of the dust consequent to a low velocity. The spray nozzles should be capable of giving the finest droplets possible. To avoid hand-cleaning in the spray chamber, it would be advisable to remove the sludge with a screw conveyor direct to the filter. If possible, all liquors should be filtered before being allowed to enter a pump since the incrustation and plugging of pumps has been a cause of many delays and shut downs.

A fan should be placed at the final outlet for the gases. The gases should then be free from all dust, cool and small in volume.

The condenser-evaporator unit would have but one pass. It would be built in duplicate by being divided by a center partition wall with the necessary dampers to permit one side being cleaned while the other side remained in operation. This would make continuous operation possible.

#### ELECTRICAL PRECIPITATION

As was mentioned under the discussion of the experimental plant, the three passes of condensing tubes are used for condensing the vapor and coalescing the precipitated mists so as to remove the water with its dissolved potash from the system. Also it was stated that possibly 60 to 75 pounds of precipitated mist per minute are carried out as an entrainment loss.

In the experimental work on these exit gases it was found that the potash salt carried in solution in the water was not all that was leaving the treater, but at times there were large amounts of potash fume escaping that had apparently resisted the wetting process. This was a great disappointment as it was supposed that if enough water were present during the process of condensation, every particle of dust and potash fume would act as nuclei, and in order to collect all the potash it was only necessary to provide means for collecting all the condensed water particles. If this were the case the small amount carried out by entrainment would not be serious; that is, it would be possible to reduce the loss to possibly 10 per cent, thus giving a 90 per cent recovery.

There are numerous ways of collecting the residual mist, such as condensers, gas scrubbers, coke towers, excelsior beds etc., but the discovery that considerable potash fume had resisted the process of wetting necessitated a different procedure altogether. The application of electrical precipitation to these gases was suggested through the experience of Mr. P. S. Taylor<sup>1</sup> at Riverside, where he was closely connected with the development of the Cottrell electrical precipitation process for the precipitation of the dry dust.

The matter was accordingly taken up with the Western Precipitation Co. of Los Angeles, and they very kindly loaned the necessary equipment and helped conduct a series of experiments on the electrical precipitation of the exit gases.

Without going into a lengthy discussion of these experiments, it may briefly be stated that it was found possible to remove practically all the potash fume contained in the gases, and that at times the water collected in the precipitation tubes carried very little more potash than the regular condensates of the condenser-evaporator, while at other times this precipitated liquor would carry eight to ten times as much potash. This showed that the potash fume in the one case had been efficiently wetted and removed by the process of condensation, while in the other case the potash fume had apparently resisted wetting.

It has been suggested that possibly the reducing condition of the kiln or the presence of the unconsumed fuel might be the cause of this condition. Undoubtedly it is a surface phenomenon, and unfortunately it has persisted in spite of the efforts made to correct it. Whether the presence of dry fume in considerable per-

centages is or is not the usual condition is a matter for further investigation. It seems doubtful, however, that it can be entirely eliminated. In any case, the use of the Cottrell process for the final scrubbing eliminates the possibility of the escape of this fume, and does away with the necessity of the numerous passes necessary with the present condenser-evaporator system to collect a large part of the already condensed mist.

The cool, saturated, foggy gases passing through the precipitation tubes seem to give the ideal conditions for complete electrical precipitation, the voltage necessary being comparatively low and the rate of flow of the gases relatively high. This calls for the minimum number of pipes, electrical connections and other accessories. By having the fan at the exit, the insulation of the electrical connections is greatly simplified.

In the permanent installation these electrical precipitation tubes would be made of cement tile, since their surface would be constantly wetted and conducting. Thus the whole installation would be of concrete construction with the exception of the condenser-evaporator tubes and flue sheets. This is an important consideration at this particular time.

#### HANDLING OF LIQUORS

The crystallizing evaporator would probably be placed in the dust flue in front of the spray chamber. The steam from the evaporator could be returned to the flue so that practically all of the heat would be conserved.

Instead of using gypsum for removing the  $\text{CO}_2$  and increasing the  $\text{SO}_4$  in the filtered liquor, it would be possible to substitute strontium sulphate or celestite. The precipitated strontium carbonate could be dissolved in nitric acid, the solution concentrated and the anhydrous strontium nitrate precipitated from the boiling liquor.

As will be seen from the diagrammatic sketch, Fig. 7, this combination process is very simple and every provision has been made for continuous operation. The coarser particles of dust will be deposited in the spray chamber and removed directly to the filter by a conveyor. Finer dust will lodge in the condenser tubes, and that portion which is not washed out by the condensates can be easily removed by shutting down but one-half of the plant. The cool gases going to the electrical precipitator are thoroughly saturated with water vapor and will carry in suspension a large amount of condensed water in the form of mist. This mist will be precipitated on the sides of the tubes and form a water film for the collection of the dry fumes which will also be caught. The gases passing through the tubes being already saturated and in the course of cooling are unable to absorb more water vapor, so there is no possibility of losing the water film by evaporation. Since there can be no concentration without evaporation, there can be no incrustation of salt in the tubes.

It will be noted in going over the amounts of water collected and ejected from the treater that the maximum amount of potash salts in the final liquor is very small—not exceeding 2.5 to 3 per cent  $\text{K}_2\text{SO}_4$ . This of course necessitates a cheap method of evaporation, which is provided by the condenser-evaporator.

The precipitated liquors from the condenser and the electrical treater, carrying the soluble salts in solution and the fine dust in suspension, will be drained through

<sup>1</sup>"Electrical Precipitation of Cement Dust," *Journal of Electricity, Power and Gas*, Vol. 32, pp. 219-223, March, 1914.

a water seal to the same filter as is used for filtering the sludge from the spray chamber. This simplifies the pumping and piping arrangements and brings together all of the insoluble portion of the collected sludge into one filter cake which can be returned to the kiln. The recombined potash and trapped solution will be contained in this cake, both of which will be quite easily volatilized in the kiln. Of course the insoluble potash would not volatilize so easily, but whatever the treatment necessary for the insoluble potash contained in the sludge, the filter cake presents a convenient form for further treatment.

#### CONCLUSION AND ACKNOWLEDGMENTS

Thus, from the experience gained in operating the present experimental plant there has been evolved a simple and comparatively inexpensive installation for the complete recovery of the soluble potash salts and dust from the kiln stack gases. The weak liquors will be evaporated and the potash recovered in a purified form and the dust returned to the kiln. The operating cost, according to the present installation, would be nearly covered by the value of the returned dust, making the present actual cost of collecting the potash a very small item. In the future even this will undoubtedly be more than offset by the better operating conditions of the whole plant, as the conditions necessary for maximum potash production call for the maximum cement production and the minimum operating expense.

In closing this long, though somewhat incomplete, discussion of this system of potash recovery, it should be mentioned that the work of designing, constructing and operating the plant, as well as the experimentation, has been carried on largely by the combined efforts of L. D. Gilbert, P. S. Taylor, L. E. Elder, and the writer. Mr. C. Leonardt, the president of the Southwestern Portland Cement Co., has been more than generous in providing the necessary funds, and it is largely his great interest and enthusiasm that has made possible the recovery plant and the experience above recorded.

Victorville, Cal.

## The Brown Process for Cement and Potash

WE HAVE received from Mr. Chester Huntington a paper on the process for making cement and potash from feldspar and limestone invented by Mr. H. E. Brown and covered under U. S. patents Nos. 1,123,841, 1,123,864 and 1,124,238. Owing to lack of space we can give but an abstract of the original article and the improvements claimed for it.

Feldspar and limestone are broken in a jaw crusher, mixed, and fed with coke or hard coal into a blast furnace and fused. The potash passes off with the furnace gases and is carried to a dust-collecting apparatus where most of the potash is precipitated in the form of carbonate, oxide and some sulphate.

The molten mass is tapped and run upon a granulating and cooling device where it is sprayed with a solution of magnesium sulphate. The granulated material is dried by the heat of the clinker and is carried to the bins of the cement grinding apparatus.

It is claimed that the cement so produced is of a superior quality due to the excess of silica in colloidal form and to the thorough fusion which eliminates free

lime. This avoids continued chemical action after the cement is set and renders it especially adapted to the construction of sea walls, docks and concrete ships. It may be made free from iron. Tensile strength tests show a higher average than Portland cement. Over 75 per cent of the total potash content may be recovered from the gases. That is, the inventor claims to liberate over 85 per cent of the potash in the change and that a precipitation of 90 per cent may be expected in the recovery apparatus. In experimental practice so far with high-potash feldspar a dust containing over 55 per cent potash was found in the collector.

A further claim is that the cost of a complete potash and cement installation will not exceed 70 per cent of the cost of a cement plant of the same capacity owing to the elimination of preliminary grinding of rock and coal and the consequent reduction of power requirements. The blast furnace should cost less than rotary kilns and take up less room. The housing requirements including the dust collector should not exceed those of a cement mill built on current lines. The grinding of the clinker is by standard methods.

The operating costs should be less than those of a Portland mill, owing to the avoidance of preliminary grinding and because gases from the top of a closed blast furnace may be more economically utilized than the gases from rotary kilns. It is held to be within the possibilities that a well designed plant can be made to supply all its power requirements from waste gases. In short it is claimed that by this process a superior cement is produced at a lower capital outlay and at a less cost per barrel than Portland cement, even if all dust-collecting costs are charged against the cement, and that it makes a vast quantity of potash available as a by-product. In plants that are favorably located it is held that 15 to 18 lb. of potash may be produced to each barrel of cement.

## Literature of the Potash Industry 1912-1917

By F. W. BRUCKMILLER

THE following general review of the potash literature is an attempt to collect in concentrated form the essential statements of the more important articles published from 1912 to 1917. No attempt is made to make an exhaustive report, but it is believed that the articles generally available have been listed. The statements under each reference are just as the writer made them:

#### GENERAL

Cameron (1) points out that as a conservation scheme kelp is of more importance than saw mill or sugar house wastes. The conservative estimated production is 1,000,000 tons of KCl per year from kelp; 5200 tons  $K_2O$  from sawdust; no figures available on sugar wastes. Silicate rocks and brines are not factors in the industry as yet.

McDowell (4) contends that if an American industry is to be built up, "someone must spend money," and two industries that can well afford to do so are the cement and sugar industries. Before brine development can proceed there must be a positive control of acreage.

Cresswell (5) reviews briefly the processes from all sources but gives no data. Numerous references as well as abstracts of articles on working feldspars and silicate rocks are included in the paper.

Dolbear (6) summarizes the efforts in the United States under four heads: (1) From Searles Lake; (2) from "vinasse"; (3) from kelp; (4) from silica rocks. Searles Lake presents a serious unsolved problem of the separation of KCl from a large number of other salts. The Pacific Chemical Co. is constructing a plant for the utilization of "vinasse" from sugar industry. The Kelp Products Co. is operating an experimental plant, with no output as yet.

"Other than wood ashes and vegetable refuse (7) there are four potential sources of potash in the United States; subterranean brines and salt lakes in the West, kelp, feldspar, and known deposits of the alunite type." "Assuming a satisfactory solution of the technical problems, there still remain certain economic problems to be considered, which make it doubtful if kelp will develop into a source of a large amount of potassium salts. The concentration of potash in the brines is so low in comparison to other salts that it is doubtful whether the extraction will ever be commercially possible." "There are no technical difficulties involved in the production of potassium sulphate, impure alumina, and sulphuric acid from alunite." There is no ready market for the sulphuric acid or the alumina. Feldspar investigation still goes on with no production. An industry can be established if there were a guarantee of no price cutting on the part of the Germans.

De Beers (8) groups our sources of potash under by-product and main product plants. Under the former is included wood ashes, bittern, wool, sugar, cement, blast-furnace, and under the latter, kelp, alunite, lakes, and feldspar. Production is now realized from wood ashes, bittern, notably Nebraska lakes, wool, cement, blast-furnace, alunite and kelp. Kelp cannot become a permanent source because of high cost of production. Searles Lake will be an increasing factor in the industry. No productive process for feldspar has yet been produced.

Ebaugh (9) by means of charts and tables shows conclusively the emergency resulting from the embargo on German potash. All efforts so far have been of the "war baby" type. Real success of a potash industry lies in the successful utilization of natural wells, such as feldspar, leucite and alunite.

In an editorial (10) on the potash industry it is pointed out that although natural brines, especially Nebraska lakes, are quite productive, it is doubtful if development will survive a return to normal conditions. Searles Lake presents a real factor in the industry, while kelp, after the war, will not prove a profitable field in spite of over \$4,000,000 investment, unless the Government Experimental Plant brings in positive results. Potash from rocks is difficult to extract, but it is not possible that that problem will forever remain unsolved.

Meade (11) groups the present methods used for getting potash in the United States under four general heads: (1) Evaporation of brines; (2) kelp and ashes of plants; (3) byproduct from cement, iron, beet sugar, and molasses; (4) decomposition of silicate rocks, especially alunite, glauconite and feldspar. The Nebraska

lakes which would promise most under normal conditions and which are reported at the present time to be making a large amount of money, are quite limited as to brine supply, and unquestionably they could only furnish a small part of the potash which has been shipped from Germany. The development of Searles & Owens Lakes depends on a market for soda ash and salt cake. The possibilities of the production of potash salts from kelp on a large scale do not seem to be particularly bright as a post-war proposition. The possibilities for developing an industry in connection with cement and blast-furnaces is excellent. In the processes proposed for the utilization of silicate rocks the quantity of potash produced compared with the by-product is negligible, and under normal conditions its value is generally less, so that with most of them potash is really the by-product and the other constituent the main one. Proper legislation is necessary to protect the industry from the foreign producer.

#### STATISTICS

References (12) to (17) include statistics in the production of potash salts in the United States, as well as the importations into the United States from Germany.

- (12) Phalen, Mineral Resources 1912, part II, U. S. Geol. Survey.
- (13) Phalen, Mineral Resources 1913, part II, U. S. Geol. Survey.
- (14) Phalen, Mineral Resources 1914, part II, U. S. Geol. Survey.
- (15) Phalen, Mineral Resources 1915, part II, U. S. Geol. Survey.
- (16) Gale, Bulletin 666-N, Our Mineral Supplies, U. S. Geol. Sur.
- (17) Gale, Mineral Resources 1916, part II, U. S. Geol. Survey.

References (18), (19), (20), (21), (22) contain description of the Strassfurt deposit, as well as report on recent studies on the geology, mineralogy and chemistry of the deposits.

According to Maizeres (23), the production of the German syndicate in 1911 was 9,399,269 metric tons of salt.

Maizeres (24) and MacDowell (25) give figures on production by German syndicate in 1912. Total salts mined, 11,164,000 tons salt, representing 1,100,000 tons  $K_2O$ .

The production in 1913 (26) was 13,000,000 tons of crude salt, or 1,413,833 tons  $K_2O$ .

Reference (27) gives the world's production in 1914, while (28) gives a summary of the statistics for imports into the United States during the month of May and five months ending May, 1914 and 1915.

MacDowell (4) gives German production for 1912 at 11,164,000 tons of salts; Cresswell (5) for 1911, 9,706,507 tons, Ebaugh (9) for 1913, 1,721,079 metric tons of  $K_2O$ .

Salcedo (29) discusses the potash production in Chili.

Commerce Reports (30) (31) for 1915 contain information on the developed deposits in Spain.

Kalski (32) describes the deposits in Kalusy, Austria.

The Canadian Chemical Journal (33) reviews the Canadian industry from 1850 down to the present day, with indications of lines for future development.

## SILICATE ROCKS

References (62) to (93) include articles dealing with all phases of the extraction of potash from silicate rocks, under which term are included feldspar, green-stone, leucite and alunite. This was made necessary to avoid too much repetition, since a large number of the articles deal with the extraction from more than one of the rocks. References (94) to (98) are on published bulletins.

## The Kelp-Potash Plant of the Lorned Manufacturing Company

An interview with

LESLIE H. THOMPSON, VICE-PRESIDENT

**K**ELP is a marine plant of high potash content. There are several varieties of potash-bearing kelp, but the only one that concerns the potash producers of Southern California is *Macrocystis Pyrifera*. *Macrocystis* occurs rather abundantly off the mainland and surrounding the coastal islands from Point Conception above Santa Barbara to below the Mexican border. It is attached to the bottom of the ocean by a root-like anchorage called a "hold-fast," and its stems or stripes are sometimes as much as 150 feet long. At the base of the leaf where it grows out of the stem is a pneumaticist, or bulb of air, which holds the strand of kelp on the surface of the water. The rate of growth and the growing period or seasonal growth are still mooted questions. While it is believed that kelp grows all the time, it appears that there are periods when the growth is more luxuriant than others. Our observation leads us to believe that there are two main growing periods about six months apart. The larger and better growth of the two is from July to September, the other from January to April. As a general thing two crops a year, and under some conditions three crops a year, may be harvested.

General control of the kelp beds is vested in the California Fish and Game Commission, which has surveyed,

*Macrocystis* up the coast from the Mexican boundary to Laguna, and include the islands of San Clemente, Santa Barbara and San Nicolas. The manufacturers at Long Beach harvest up the coast from Long Beach to Rincon Point. The manufacturers at Summerland harvest from Carpinteria to Naples. The territory west of Naples and the Santa Barbara Channel islands of San Miguel, Santa Rosa, Santa Cruz and Anacapa, are considered open territory.

### THE PROBLEM OF HARVESTING

The first and most unique problem before the seekers of potash from kelp was that of effectively harvesting the weed itself. It should be understood that the plant contains approximately 90 per cent water, which means that a tremendous bulk of the raw kelp must be handled before a modest amount of potash can be secured. While the methods of harvesting in use by the various manufacturers are similar in principle, there is some variance in the details. Fig. 1 shows a view of the Lorned harvester "Albion," which is equipped with two 60-hp. engines. It has a capacity of 130 tons of wet kelp on deck. The cutting apparatus consists of a horizontal cutter bar equipped with oscillating knives similar to an ordinary mower. At the end of this horizontal cutter bar, which is 12 feet long, are two vertical cutter bars 4 feet long, equipped with the same kind of knives. The cutter is lowered into the water so that the horizontal cutter bar is approximately 4 feet below the surface, and as the kelp is cut it is carried up and deposited on the deck by a draper or slat conveyor. As

the kelp accumulates in the bow of the boat under the draper, it is hauled back by means of a grab-hook operated by a winch, so that the load is kept properly distributed as fast as it accumulates. This harvester carries a crew of six men—a captain, engineer, winchman, cutterman, and two hookmen. This is a seaworthy boat, and can operate in fairly rough weather. It has a speed of nine miles an hour, and in thick kelp can harvest fifty tons an hour.

On returning, the loaded harvester docks alongside the unloading pier underneath telpher track extending out from above a receiving hop-

per. A grab-hook, built like a clam-shell bucket, having a capacity of about 1500 pounds of kelp at a grab, unloads the barge, all lines being handled from a double-drum electric hoist. The unloading is done by an unloading crew of three men. About 30 tons an hour are unloaded in this way.

### CUTTING AND CONVEYING

This receiving hopper has but a moderate capacity, it being large enough to catch merely one grab-hook of kelp and feed it through a chopper (an ordinary ensilage chopper with certain extra controls) which cuts the

FIG. 1—THE "ALBION" LYING AT UNLOADING PIER

mapped and numbered the various areas capable of being harvested. The Commission exercises supervision over the beds, closing those which have been cut while they attain a regrowth, in such a way as to conserve the supply to the greatest possible advantage. Dr. W. C. Crandall of the Scripps Institution for Biological Research is a special deputy of the commission, and at the Institution scientists are making a thorough study of the growth and habits of kelp.

The chief manufacturers of kelp products are located at San Diego, Long Beach and Summerland (near Santa Barbara). The San Diego manufacturers harvest

kelp into lengths averaging about 12 inches. The chopped kelp drops into a drag conveyor, shown in Fig. 2, motor-driven at approximately 120 feet per minute, leading in three flights 700 feet in shore to a 300-ton hopper-bottomed storage bin. This storage bin is divided into two sections with a capacity of 150 tons each. The conveyor is merely a wooden flume with a pair of link chains along the bottom, to which cross-boards or slats are bolted at short intervals. The kelp itself is very slippery—its slimy exudation effectually lubricates the surfaces of contact between chain or flight and conveyor bottom.

In the above manner the kelp is cut, conveyed and discharged into an empty section of the storage bin as rapidly as it is unloaded from the barge.

Heaped kelp bleeds a yellowish, slimy substance, which contains about as much potash as the weed itself. This juice dripping from the storage bin is carefully caught on a tight subfloor, and drained into a concrete supply tank from which it is pumped into pans placed below and above the hot end of the rotary incinerators

FIG. 2.—VIEW FROM STORAGE BIN

and evaporated to dryness by the radiating heat which would otherwise be wasted. The solids remaining are a dark purple crystalline mass containing about 25 per cent K<sub>2</sub>O.

The V-shaped bottom of the kelp storage-bin is closed by a series of loose, horizontal boards, directly underneath which runs a drag conveyor such as formerly described, leading to the kiln room. One laborer is in the storage bin at all times, feeding or regulating the flow of the slippery sea weed to this conveyor. As the contents of the bin are unloaded back to a slope where considerable hoeing is required to keep a constant discharge, another one of the horizontal boards is removed at the toe of the slope. In this manner the bin is progressively emptied at a rate depending upon signals from the kiln room.

#### INCINERATING THE KELP

A stream of wet kelp coming in this manner from the storage bin is discharged into four rotary dryers by one of a pair of tilting-box feeders (Fig. 3), set between and above their hot ends. Thus at intervals of about 14 seconds either kiln receives a charge of 15 pounds

of material. The kilns themselves are merely unlined horizontal cylinders of steel plate, 42 feet long by 7 feet in diameter, set at a slight incline from the hot end downward toward the discharge end ( $\frac{1}{8}$  of an inch per foot), so that the contents will progress slowly forward as the cylinder rolls. Twelve rows of hooks, as shown

FIG. 3. TILTING BOX FEEDER

in the sketch, Fig. 4, are affixed to the interior of the shell in order to lift the wet shreds and drop them through the heated air within the kiln.

The kiln itself is fired by two oil burners, the fuel supply coming from wells in the immediate vicinity. The oil flame is confined within the limits of a relatively large "Dutch oven," 21 by 12 by 9 feet, set directly in front of the kiln itself. In this way a stream of gases of combustion and hot excess air enters the kiln, coming first in contact with the wet kelp at about 1400 deg. F. These gases partly dry the material in their passage, leaving at the far end loaded with moisture and cooled to a temperature of approximately 250

FIG. 4. INTERIOR KILN CONSTRUCTION

deg. F. The temperature of the exit gases is kept under constant observation by means of a recording pyrometer; should the temperature show a tendency to rise the feeder in the storage bin is notified to increase the flow of wet material, and *vice versa*. The moisture content of the weed discharged from these preliminary driers has been reduced from 90 per cent to about 25 per cent, the actual evaporation depending in large part upon the amount of work which can be performed in the incinerator, described later. The

appearance of the kelp at this point is markedly changed; the wet, green, slippery plant is now shriveled into dark brown, tough, leathery pieces, dry to the touch. Sometimes the leaves have burned to a char around the edges; these thin brittle borders are then pulverized during their travel through the kiln and are largely swept away with the furnace gases as dust. The moisture evaporated in these dryers is approximately 13 pounds per pound of fuel oil, using a fuel oil of 12 deg. Baumé, specific gravity 0.986, calorific power 18,500 B.t.u. per pound.

Two incinerators receive the discharge from the four dryers. These are merely rotary kilns 40 feet long and 5 feet in diameter, similar in construction to the preliminary dryer, except that they have no furnace or oven, the oil flame shooting directly into the drum. In this kiln the flame further dries the kelp and burns off the volatile hydrocarbons, producing a hot, grayish charcoal containing 35 per cent  $K_2O$ . The discharge falls into wheel-barrows and is immediately spread in long narrow ridges or "wind rows" on a cooling floor of concrete, where its heat quickly radiates into the atmosphere.

#### RECOVERY OF DUST FROM DRYERS

Furnace gases and moisture are drawn off from the rotary dryers by suction fans placed at the discharge end. The size of these fans averages 42 inches in diameter, with a capacity of 6000 cubic feet per minute, speed 900 r.p.m. Approximately 10 horsepower is required to operate each fan. A similar fan is used at the end of the incinerators to produce a draft necessary to complete combustion. Both in the preliminary dryers and in the incinerator a portion of the charge breaks into the finest particles, which are swept out by the furnace gases. This dust is of course quite valuable, and at the Lorned Manufacturing Co. the furnace flues lead to a series of brick dust chambers where the velocity is reduced to such a point that nearly all the dust is precipitated. At the end of the dust chamber the smoke passes through sprinklers to wash it thoroughly before allowing it to escape into the air. An average of 15 tons of dust, having a content of 30 per cent  $K_2O$ , is recovered from the dust chambers each month.

#### PRODUCT USED AS FERTILIZER

After the charcoal has cooled it is fed into a screw conveyor leading to the crushing plant, which is equipped with a Williams mill having a capacity of about 2000 pounds per hour. The resulting product, amounting to approximately six tons per day, is bagged on platform scales in sugar sacks containing 125 pounds each of fine ash. The sacks are stored until shipment in a nearby warehouse. A ready demand exists in the Southeastern fertilizer market.

The process as described above is admittedly crude. Many valuable products can be made from kelp, which are absolutely lost by this method. It has, however, the advantage that it produces potash, which is doubtless the one product most keenly needed just at present, in a plant readily operated without close technical control or a staff of highly skilled operatives.

As to the future of the industry, one may turn to various authorities. Meade<sup>1</sup> estimates that the efficiency

of the rotary dryers amounts to 70 pounds of water per gallon of oil, and that 1900 gallons of oil must be burned to produce one ton of potash. He therefore concludes that "the possibilities of the production of potassium salts from kelp on a large scale do not seem to be particularly bright as a post-war-time proposition. The cost of . . . fuel alone under ordinary conditions would eat up most of the price obtained for the product." On the other hand, Laucks<sup>2</sup>, citing his experience in drying kelp in the Northwest, quotes a harvesting cost of 42 cents per ton of kelp, unloading at 6 cents, and drying from 25 to 50 cents per ton of green kelp, using a rotary drier and hogged wood-waste as a fuel. Under these conditions, which evidently represent prices before the recent inflation, and which happily may be attained again, Laucks thinks that a product containing 28 per cent KCl, 2 per cent nitrogen, and 10 per cent water can be worked at a profit if the price for 80 per cent muriate remains above \$35 per ton. J. W. Turrentine, the government expert in charge of their experimental plant, on the other hand, writes,<sup>3</sup> "The giant kelp of the Pacific Coast still offers the best promise of supplying the proper conditions for the establishment of a domestic potash industry. Thus, they occur in sufficient quantity, they are accessible, and the product under normal conditions may be delivered at the market—the Atlantic seaboard—at a charge for freight that is not prohibitive."

The real truth may lie somewhat between these optimistic and pessimistic statements. Purely as a producer of potash by evaporating methods, kelp is at a distinct disadvantage against the Nebraska lakes. For instance, each has to evaporate about the same amount of water to get a ton of  $K_2O$ , and so far they have even chances; but it evidently costs much more to harvest a marine plant than to pump salt water. The future of kelp seems to lie in the recovery and use of the various by-products. The wet fermentation method developed with such marked success by the Hercules Powder Company,<sup>4</sup> produces potassium chloride, acetone, iodine, ethyl acetate, propionate and butyrate in commercial quantities, but requires a very expensive plant and high technical equipment. The dry distillation process now being developed by the United States Department of Agriculture in their experimental plant at Summerland, California, and in the forest products laboratory at Madison, Wisconsin, may prove more economical in first cost than the other. Potassium chloride, iodine, charcoal and distillates will be the chief products, and the success of their ideas will probably depend in large part upon the uses discovered for the latter two.

#### Potash and Kali

Kali, the German word for potash, comes down directly from Sanskrit, the ancient language of the Hindoos. Kali was their name for the black destroying goddess, who had numerous arms and red-palmed hands. Her eyes were red and her face and breast besmeared with blood. The name of the city, Calcutta, is derived from Kalighat, which, translated, means Kali's landing place. No doubt, Kali is just as plain and as representative a name for burned wood as our term potash.

# The Potash Industry of Germany

Theories of Origin and Description of the Strassfurt Salts Deposit—The Present Status of the Industry—Its Economic Aspect

By WALLACE SAVAGE

POTASH is one of the most abundant of the chemical elements, constituting about one-fortieth part of the mineral crust of the earth. In the formation of the fused glassy rocks such as the granites, micas and feldspars, it has contributed to a very great extent to their weather enduring properties, upon which the maintenance of land above sea level, the habitation of man, is largely dependant. How resistant these mineral potassium silicates have been to the ages of weathering in the past is obvious upon examination of the rocky peaks of the mountain ranges, or can be deduced from analyses of the ocean brine, the continental wash waters of all ages in concentration. Sea water will be found to consist essentially of sodium and magnesium salts in its three and one-half per cent of dissolved matter. Table I gives an analysis made by Regnault of the eight most important sea brine constituents.

TABLE I—ANALYSIS OF SEA WATER

|                          | Per Cent.<br>Solids | Per Cent.<br>Brine |
|--------------------------|---------------------|--------------------|
| Water.....               | 00 00               | 96 47              |
| Sodium chloride.....     | 76 49               | 2 70               |
| Magnesium chloride.....  | 10 20               | 0 36               |
| Magnesium sulphate.....  | 6 51                | 0 23               |
| Calcium sulphate.....    | 3 97                | 0 14               |
| Potassium chloride.....  | 1 98                | 0 07               |
| Calcium bicarbonate..... | 0 08                |                    |
| Magnesium bromide.....   | 0 06                | 0 03               |
| Miscellaneous.....       | 0 71                |                    |

However, judging alone from the preponderance of sodium, magnesium and calcium salts shown here, one could not derive numerical deductions, for a great part of the decomposition products of the minerals are absorbed largely and variously in animal and vegetable growth of an unknown amount. Table II gives the weights of salts in the ashes of normal crops from an acre of ground in the order of their average proportions.

TABLE II—POUNDS OF VEGETABLE ASH—ACRE CROP

|                 | Grain | Straw  | Roots  | Tops  | Hay   |
|-----------------|-------|--------|--------|-------|-------|
| Silica.....     | 14 71 | 233 08 | 27 03  | 2 67  | 78 23 |
| Potash.....     | 14 39 | 32 73  | 142 66 | 88 82 | 38 22 |
| Lime.....       | 2 24  | 27 62  | 46 24  | 72 14 | 44 45 |
| Phosphate.....  | 35 76 | 10 56  | 25 77  | 28 80 | 15 12 |
| Sulphate.....   | 0 12  | 13 15  | 46 24  | 38 81 | 9 20  |
| Chloride.....   | 0 02  | 3 55   | 12 24  | 49 75 | 4 06  |
| Magnesia.....   | 7 00  | 12 14  | 18 16  | 9 58  | 7 09  |
| Soda.....       | 7 05  | 1 21   | 17 31  | 16 76 | 12 05 |
| Iron oxide..... | 1 11  | 5 96   | 4 35   | 2 67  | 0 58  |

In the cycles of primeval vegetation, the mineral matter of all organic life was returned to the soil upon its inevitable decay at the place of growth. However, when man ceased to be an inhabitant of the forest, and the population became engaged in urban and agrarian pursuits, the extraction of the mineral salts from the soil began on an ever-increasing scale. Upon examining the table, the effect of the modern root crops, sugar beets and potatoes, in respect to potash, will be seen to be very great, 231 lb. being absorbed to the acre. Still more important did this become, when it was found that growth ceased as the available potash etc. became exhausted. In 1860, A. Frank, chemist in the sugar

refinery of Bennecke and Hecker at Stassfurt, worked out a process for extracting potassium chloride from the overburden salts, "abraumsalze," of the local rock salt mine, the two shafts of which had been completed in 1852. The manufacture of potash salts was then instituted, which became absolutely essential as a fertilizer to the German sugar beet, potato starch and alcohol industries.

## THE STASSFURT SALT INDUSTRY

During ancient times in Germany, before the era of the manufacture of iron pipes, salt was not transported long distances, but was obtained from the nearest brine springs, which were numerous, on account of the underlying strata of rock salt located there. In the lowlands north of the Harz Mountains, the flow of ground water toward the sea, due to the water head from the mountain slopes and the impervious strata formation of the soil, gave rise to many brine springs, the sodium chloride content of which, however, though not large, was exceptionally pure—the slight content of bitter foreign salts having been dissolved and entirely carried away from the leached residues of the deposits adjacent to the underground water currents.

Starting in about 1785, many wells were drilled in different parts of Europe. Prior to 1825, enormous beds of rock salt were located at many places in Wurttemberg, Hess, Baden, Lothringia, Langenberg, Kostritz, Koburg-Gotha, etc. Crude salt soon became so abundant that its main costs were in government tax fees and transportation charges. In 1839, the Konigliche Saline at Stassfurt gave up evaporating brine and began prospect work to determine the local availability of mineral salt as pure as that derived from their spring brine. In August, 1843, their drill struck salt at a depth of 832 feet, and after years of difficult work they drove into solid salt about 1000 feet, stopping on May 31, 1851, without reaching the base of the deposit. The well was a disappointment qualitatively, as the brine obtained from it had a very bitter taste.

Geheim Bergrat von Carnall decided that a shaft would be necessary to determine whether a separate layer of pure edible salt was situated at the source of the brine spring. Handelsmeister von der Heydt ordered two shafts sunk, which were started in the winter of 1851. At the ceremonies celebrating the opening, a crier went about Stassfurt calling: "Fellow citizens! Great opportunities will arise in the future for our industrial expansion! Just as there has been in the case of the sugar refinery, so will there be in this far more important undertaking!" How majestically this prediction was to be fulfilled could not have been foreseen in these days of wood fuel and ample supplies of potash from wood ashes. It was exactly these accompany-

ing mineral salts, potassium and magnesium chlorides, an undesired impurity in table salt and without a market at the time, which were to become the corner stone of German strength in international commerce in chemicals, the absence of which were indicated initially by the purity of spring brine, because in reality, they were sealed from the ground water by impervious strata of clay and gypsum but for the protection of which they would long since have been dissolved by the ground water and disseminated far and wide.

#### PROSPECTING THE STASSFURT DEPOSIT FOR POTASH

From the amount of boring that followed in subsequent years, the deposit of potassium salts appears to cover an area of one hundred square miles, principally located in Anhalt and Prussian provinces of Saxony and Hanover. At an early date Anhalt, recognizing the agricultural and financial value of such deposits, declared the rights of exploration a state monopoly, which was later contracted to a few private companies. In Saxony, prospecting rights were free and the mining concessions belonged to the first discoverer of the deposits without regard to the owner of the surface soil. According to the laws of Hanover, the property holder owns all the mining rights.

Under such a variety of laws, the deposit has had unhampered exploitation. Speculators have paid as high as \$12 per foot for diamond drill cores to establish their claim for concessions. Stock companies were formed in great numbers. The older companies, fearing overproduction and falling prices, banded together against newcomers. The earlier members of the syndicate, with the year of their starting mining and their production allotments for the four following divisions are given in Table III.

- Class I Products more than 48 per cent K<sub>2</sub>O.
- Class II Products 48-18 per cent K<sub>2</sub>O.
- Class III Products 18-12 per cent K<sub>2</sub>O.
- Class IV Products less than 12 per cent K<sub>2</sub>O.

#### THEORY OF THE FORMATION OF THE STASSFURT SALT DEPOSITS

The colossal size of the salt deposits which have been disclosed in Northern Europe has created much speculation upon the part of geologists and chemists as to the manner of their formation. For detailed discussions on the subject, the reader should consult the German treatises<sup>1</sup>.

Summarizing the studies of his predecessors, C. Ochenius explained the origin of the deposit by the evaporation of sea brine in land-locked basins near the

ocean shore at the time of the Permian formation, which bodies of water were shut off from the open ocean by sand bars at the connecting inlets, thus forming land-locked salt lakes. Such a formation can be seen at the present day on the east side of the Caspian sea. The surface of this Caspian lake, which is connected to the open sea by a shallow canal 225 yards wide and 1 yard deep, is 585 square miles in area with a depth of 16 yards. In the summer a thick layer of salt crystallizes out. Upon comparison of the solubility curves in Chart I with the analysis of sea water, Table I, it will be seen that ocean brine is 10 per cent saturated with sodium chloride and only 1 per cent with magnesium chloride. While intra-ionic and physical af-

CHART I.—SOLUBILITY CURVES

fects vary the solubility of these salts in the presence of each other, it can be readily seen that a dead sea would have to be concentrated one hundred times by means of evaporation and decrease in volume, due to the space occupied by the deposited sodium chloride, before the bitter salts would separate from their solution.

Upon inspection of the salt deposits at Stassfurt, thousands of segregated strata of salt from 3 to 4 inches thick will be found. During the changes in the weather, when probably the "September gales" dashed the sea over the inlet bars, new brine charged with lime salts entered the dead sea and there was immediately deposited a thin blanket of anhydrite (CaSO<sub>4</sub>) which has become known as the year ring from analogy with the lines in tree growth. The number of these rings indicates that ten thousand years were occupied in the deposition of the rock salt and in the accumulation of the saturated solution of magnesium and potassium salts.

Finally, either the bars grew to greater size or the weather grew milder and the barriers completely isolated the lake of accumulated minor brine salts from the ocean. Polyhalite (K<sub>2</sub>SO<sub>4</sub>, 2CaSO<sub>4</sub>, MgSO<sub>4</sub>, 2H<sub>2</sub>O) first crystallized, then kieserite (MgSO<sub>4</sub>, H<sub>2</sub>O), next carnallite (KCl, MgCl<sub>2</sub>, 6H<sub>2</sub>O), and then fortunately clay, gypsum, sandstone and diluvial and alluvial formations sealed the deposit securely as is shown in Fig. 1 of the Leopoldshall deposit. The period for the entire formation down to the 3300-foot level of the salt deposit has been estimated at about 15,000 years.

A few investigators believe that the ocean was not the source of the brine and that the salts were the direct decomposition products of the rocks from the Harz Mountains. An example is offered at present in the case of the historic Dead Sea and the river Jordan. In recent times van't Hoff, in cooperation with many other chemists made an investigation on the crystal-

Ochenius, "Die Bildung der Steinsalzlager und ihrer Mutterlaugensalze." Walther, "Das Gesetz der Wurtenbildung." Van't Hoff, Sitzungsber d. Kgl. preuss Akad. d. Wissenschaft. Zu Berlin 1897-1908; "Zur Bildung der Ozeanischen Salzlagernungen."

For this reason, hot solutions and cold crystallizations are made, the temperature increasing the solubility several per cent of both these salts. Sodium chloride does not become materially more soluble upon boiling, so that what dissolves does not crystallize out on cooling, but passes away with the mother liquor. The scheme of the process used in the average refinery is given diagrammatically in Chart II. Sylvine is a secondary salt found at many places where ground water has had limited access and has carried off the more soluble magnesium salts, leaving sodium and potassium chlorides. This is easily refined by solution in hot brine, potassium chloride being alone supersaturated upon cooling. While many elaborate types of digesters have been developed for use in this industry, space will not be taken for their description.

About nine years ago there arose an illuminating price controversy between the Schmidtman Company

temperatures during the period of formation was from 77 to 163 deg. F. If the brine corresponding to the deposited salts should be superimposed over the deposit, it would be fifty miles deep, which would indicate that an average of one rod of water was evaporated annually. Reasoning from such figures, one is led to con-

# The Cottrell Process for Potash Recovery\*

## A Description of the Collection by Electrical Precipitation of the Volatile Vapors of Alkali Salts from Iron Blast Furnaces and Cement Kilns

By LINN BRADLEY

Chief Engineer of the Research Corporation

THE subject of potash recovery is becoming of more universal interest to the public as well as to the technical man. The daily press and the magazines frequently refer to what is being done and to what should be done in this country in order to offset and decisively defeat the Kaiser and his followers. Recently several news items and editorials have appeared in the metropolitan press calling our attention to what is being accomplished in England toward making their country independent of Germany, and it appears that the British Government has furnished large sums of money to assist in recovering potash from their iron blast furnace gases. It is predicted that this source will enable England to obtain enough potash to equal her entire pre-war importation from Germany. France is reported to be as keenly awake to the possibilities along this line and we may see the time when France will be recovering large quantities of potash from iron ores which Germany has made such strenuous efforts to control. However, it is not surprising that interest in potash should increase, when we consider that this is the one big economic weapon which Germany has relied upon to regain her place in the sun after the war. She boasts that all countries will have to depend on her for potash. She claims that other countries can not produce potash to compete with that supplied by Germany. But in this as in many other instances her reasoning is based on lack of information as to facts and possibilities.

The recovery of potash in this country is making rapid strides. The industry may be roughly divided into those plants in which the recovered potash is the main product and those in which the potash is recovered as a by-product. In this paper the latter phase will be considered as it is believed that while the largest immediate tonnage may be obtained from desert lakes, kelp, alunite and a few other sources, nevertheless a study of the economic problems will show that the surest way of making our potash industry a permanent and enduring one, able to supply all of our requirements even against German competition, is to develop and rely upon the by-product potash.

### FIRST CEMENT PLANT INSTALLATION

After the installation of the Cottrell processes at the plant of the Riverside Portland Cement Company in California was placed in operation for the purpose of eliminating the dust nuisance, it was noticed that the material collected in various parts of the precipitator differed in fineness. Natural inquisitiveness then called for an analysis of these products to determine if any

impurities in the raw mix had become concentrated in any portion of the dust. The alkalies increased with the fineness of the material as shown by screen analyses. At that time considerable light fume was escaping from the precipitator exits and the suggestion was made and urged that some of this material be collected and analyzed as it might show even higher alkali content, since having been interested in agricultural and fertilizer problems it seemed to some of us that potash might be found in the escaping fume in percentages such as would warrant its recovery. Thus the first commercial potash recovering plant in this country was established. The engineer in charge of this work was Mr. W. A. Schmidt of Los Angeles. Since that time a number of improvements have been developed and the commercial success of the potash plant at Riverside has been the cause of several other cement plants installing potash recovery plants.

### INVESTIGATION MADE ON BLAST FURNACE DUST

Early in 1912 the Research Corporation of New York started to develop the Cottrell processes and apply them to various plants in the eastern portion of the United States. Shortly after work had been begun, a paper was read and a demonstration given at a meeting of the local section of the American Chemical Society near Allentown, N. J. The next day arrangements were made for a visit to the South Bethlehem plant of the Bethlehem Steel Company. Having in mind the experiences of the Riverside cement plant, curiosity was aroused by the appearance of the gases coming from the tall brick stack connected to the boilers. An investigation was undertaken by Mr. R. J. Wysor and this resulted in extensive investigations thereafter to determine the possibility of cleaning these gases by the Cottrell processes and recovering whatever of value could be obtained from the collected material. Mr. Wysor has published a very able and valuable article in the *Transactions of the American Institute of Mining Engineers* (1917) giving a great deal of data on ores, fluxes, slags, potash balances and other items directly related to the recovery of potash as a by-product of blast furnaces. His paper probably served as an inspiration for much of the work which has been undertaken abroad.

Analyses of iron ores, cokes, limestones and dolomites show a wide variation in potash content, and it is therefore advisable for one interested to make sure that his raw materials are sufficiently rich to warrant a potash recovery plant. Furnaces which produce a large tonnage of slag per ton of iron on account of the iron content of the furnace charge will, of course, carry more potash into the slag than furnaces which produce

\*A paper read at the Fourth National Exposition of Chemical Industries, New York City, September 25, 1918.

a relatively small volume of slag, other things being equal except for composition of the charge. Some iron ores carry as high as 60 per cent of iron and are practically devoid of potash. Some coke have a low ash and are low in potash. Some limestones and some dolomites may be quite pure. If, therefore, the ores are uniform and properly prepared and the fuel and flux are properly proportioned, the slag volume will be small and the potash in the gases may likewise be negligible. On the other hand, if the iron ore carries as much as two or even one per cent of potash ( $K_2O$ ) and the coke ratio is high and it and the flux contain as much as .25 to .50 per cent of potash, quite a large quantity of potash will be volatilized and carried off by the gases from which it can be recovered. The high temperature in the blast furnace and the length of time under treatment allows the silicates to be decomposed more readily than in a cement kiln where the temperatures are not so high. The potentialities of the by-product recovery from blast furnaces would, therefore, seem to surpass the possibilities of the Portland Cement Industry in this regard.

Numerous attempts have heretofore been made to recover potash from silicate rocks. The investment and operating cost, especially for fuel, are hard to overcome if one endeavors to volatilize the potash and recover it and nothing else. It therefore seems that the best way to recover the potash from these silicates by heat treatment is to charge these silicates into existing furnaces along with the regular charge and recover the potash as a by-product, thus eliminating the investment and operating cost for new and separate furnaces. This would be profitable up to a certain point, beyond which this practice would, however, not be desirable.

Since the investigations referred to were begun at South Bethlehem, numerous other furnaces have been investigated and potash balances made. Iron ores have been found in abundance in Alabama which carry from one to as high as three per cent in potash and carry enough iron to make them highly suitable for this purpose. The following tables show the results of one investigation.

#### PERCENTAGE ANALYSES OF MATERIALS

| Material  | Fe    | $SiO_2$ | $Al_2O_3$ | $CaO$ | MgO  | Ash   | Carbon | $Na_2O$ | $K_2O$ |
|-----------|-------|---------|-----------|-------|------|-------|--------|---------|--------|
| Ore No. 1 | 46.36 | 17.42   | 4.19      | 5.03  | 8.33 | ..... | .....  | 0.62    | 1.27   |
| Ore No. 2 | 54.69 | 12.78   | 3.49      | 4.04  | 6.00 | ..... | .....  | 0.39    | 0.74   |
| Stone     | ..... | 1.56    | 0.58      | 46.24 | 7.25 | ..... | .....  | 0.64    | 0.26   |
| Coke      | ..... | 5.82    | 3.49      | 0.51  | 0.24 | 13.01 | 86.15  | 0.39    | 0.32   |

#### CHARGED INTO BLAST FURNACE

| Materials | lb. per Ton Iron | Total lb. $K_2O$ | Per Cent. of Total |
|-----------|------------------|------------------|--------------------|
| Ore No. 1 | 3,115            | 39.56            | 61.0               |
| Ore No. 2 | 1,168            | 8.65             | 13.2               |
| Stone     | 1,440            | 3.74             | 5.8                |
| Coke      | 4,059            | 12.97            | 20.0               |
| Total     | 9,773            | 64.92            | 100.0              |

#### SUMMARY

|                                                                                                      |       |
|------------------------------------------------------------------------------------------------------|-------|
| Total $K_2O$ charged into furnace per ton of iron produced, lb.                                      | 64.92 |
| Lost in slag per ton of iron produced, lb.                                                           | 11.60 |
| Lost as fume from gas leaks per ton of iron produced (estim.), lb.                                   | 1.16  |
| Total potash recoverable from gases per ton of iron produced, lb.                                    | 52.16 |
| Total potash in dust in gases as per analyses, per cent                                              | 34.11 |
| Water soluble potash in dust in gases as per analyses, per cent                                      | 32.10 |
| Portion of total potash in dust, which is water soluble, per cent                                    | 94.11 |
| Total water soluble potash recoverable per ton of iron by collecting the dust in the flue gases, lb. | 49.09 |

|                                                                                                                   |          |
|-------------------------------------------------------------------------------------------------------------------|----------|
| Total water soluble potash as above per 500 tons iron per day, lb.                                                | 24545.00 |
| Total water soluble potash as above per year of 350 days, tons                                                    | 4295.37  |
| Portion of total potash charged into furnace which is recoverable from gases in water soluble condition, per cent | 75.62    |
| Safe estimate of above amount recoverable in operating practice, per cent                                         | 80.00    |
| Safe estimate of above amount recoverable as above per year of 350 days, tons                                     | 3436.29  |

A study of the above figures will show that it is desirable to keep the potash content of the raw materials up to the highest point and to keep the slag volume and potash content as low as possible. It is clear that if the slag volume remained constant as well as its analysis that if only 11.6 pounds of potash had been contained in the furnace charge there would have been nothing available for collection. With suitable slag volume and potash content and a rich potash charge, the recovery of potash in quantities worth while is readily obtained. Sodium chloride has been found helpful in liberating the potash in such way that it is recoverable in the dust in a water soluble form. While working at a cupola furnace in which sash weights were made from old tin cans and other metal waste, it was found that the use of common salt, sodium chloride, greatly increased the fume volume and density and this later was shown to be due to the fact that chlorides of lead, tin and zinc were formed and readily volatilized as such. The use of salt has been extended to cement kiln practice and to other uses in connection with the recovery of silver, lead and zinc from low grade ores and tailings, the values being recovered from the gases after volatilization as chlorides.

Consideration of data such as presented in the tables given below resulted in an effort being made to find raw materials suitable for making iron and yet carrying high percentages of potash. Samples of ores, fluxes and coke were obtained from a number of furnaces and other sources, and later on this work was carried on much more extensively by the Bureau of Soils of the Department of Agriculture. It is probable that Mr. Frederick Brown of that Bureau has now collected data on nearly all of the raw materials available for iron making and that if such data were made public in the near future, it would be of great assistance in connection with the problems under consideration. Personal efforts to find materials such as described developed the fact that in the eastern part of Alabama there is a very large tonnage of iron ores carrying in some cases an average of one per cent of potash and in other instances an average of about 1.80 per cent of  $K_2O$ , several analyses showing a content of over 3 per cent  $K_2O$ . I am indebted to Dr. J. S. Grasty for having brought these ores to my attention and for much of the data on their iron and potash content as given later in this paper. Mr. M. W. Bush, President Shelby Iron Company has also contributed data on the iron situation of the South and the values of these iron ores in furnace operations. I have examined these properties and have interviewed blast furnace operators who have used them in their furnaces and hold the opinion that they constitute an asset of importance to the nation as well as to interested parties. They should receive the consideration of the Government in connection with our war

problems and likewise our post-war problems so as to assist in rendering our country absolutely independent of Germany. The ores carry an average of from 48 to 52 per cent of iron, are very uniform, easily mined and shipped as they are directly on the railroad, and operate satisfactorily in the furnace producing good iron at low cost. Their potash content also acts as a desulphurizer, thus improving the grade of iron. The phosphorus content is very low.

The following table has been compiled to show the economic importance of these ores as a source of potash, the figures having been based on experience at several other furnaces as well as on the data obtained in connection with these particular ores and at various iron furnaces in the South. The tables has been submitted to experienced iron blast furnace operators for suggestions and criticisms. For comparison, other ores have been included in the table. The composition of the high-potash iron ore has been taken from the average of over one thousand tons of such ore shipped to furnaces on which  $K_2O$  was determined for each car of this particular shipment.

| Value per annum at \$500 per ton of $K_2O$ .....     |      |       | \$3118500     | 489000       | 703000         |
| Value per annum at \$100 per ton of $K_2O$ .....     |      |       | 623700        | 97800        | 140600         |

The total production of pig iron in this country is such that about 200 furnaces of such size as referred to above would be required to meet our requirements if the furnaces were of the same capacity. So it is easy to see that we now have sufficient furnace capacity to produce annually over 1,500,000 tons of potash per annum, far in excess of our pre-war requirements. The difficulty lies in the fact that we have not found that all furnace burdens carry the amount of potash shown under the No. 1 column. If the furnace charges and operations could be adapted so that one-fifth of the amount, or 300,000 tons, could be produced this would meet our needs without assistance from any other source. The three constituents of the charge, ore, stone and coke, contain more or less potash. By using those raw materials which carry more than usual amounts of potash, our recoveries can be considerably augmented. In cases where ores are smelted which are excessively limy, feldspar, potash bearing slate or

other potash bearing silicates could be fed into the furnace and thus increase the potash content of the furnace burden.

#### BY-PRODUCT POTASH FROM FELDSPAR CEMENT

Mr. H. E. Brown, a chemical engineer of New York City has developed a process for making a special cement from the slag obtained from a blast furnace and at the same time recovering water soluble potash from the gases. He charges limestone, coke and feldspar into the furnace. Now if iron ores of suitable kind could be used for a portion of the raw material, it might be possible to produce potash from the gases, also pig iron, and a slag which could be readily converted into a marketable cement. As the market varies with the supply and price, the furnace charge could be varied so as to increase the potash and reduce the iron or vice versa. The process has been developed to the extent that both potash and the special cement can be produced but investigations looking to a reduction in the operating cost have not been completed. It appears, however, that with an assured market for the cement at fair prices, the process can be operated successfully and show a good return on the investment, especially when the price for potash is high. In this connection, it seems that consideration might well be given to the use of powdered coal introduced through the tuyeres and thus reduce the coke required and possibly doing away with it all together. It would materially reduce operating costs and increase production and recoveries.

#### POTASH FROM THE GEORGIA CAMBRIAN SLATES

It is natural to look to feldspar and other potash bearing silicates for our potash. The cost of mining and grinding feldspar is one obstacle to be overcome which is not an obstacle for instance in the Cambrian slates of Georgia. It has been suggested also that efforts be made to recover potash from the tailings dumps in the Cripple Creek District of Colorado, these tailings carrying as high as 7 per cent of  $K_2O$ . Investigations as to the feasibility of this are now under way. Sufficient progress has not yet been made, however, to warrant any very optimistic statements. The fuel cost and the necessity for a long freight haul to the fertilizer consuming districts are large items to overcome.

Sericites and Cambrian potash bearing slates have been located in Georgia which carry potash in considerable quantity, several deposits analyzing as high as 8 per cent or 9 per cent. Laboratory investigations have shown that the potash in these raw materials was more readily rendered water soluble or volatilized by treatment with salt in a rotary kiln than the potash from feldspar. Furthermore, the amount of lime required to be added to the charge before the potash is liberated appears to be much less than required for feldspar. The cost of production is much less than in the case of feldspar and the cost of grinding is very much less and altogether these slates are much better adapted for the purpose here discussed than feldspar is. Dr. T. P. Maynard of Atlanta, Georgia, who conducted these researches and developed the properties, reports that there is an enormous tonnage available. It is also reported that a company has been treating this material in a rotary kiln, adding 200 to 300 pounds

of salt per ton of raw material, volatilizing a good portion of the potash and converting a large percentage of the balance into a water soluble compound in the clinker. Freight rates should be very low since this material is located very close to a large market, namely the cotton fields of Georgia and Alabama. Engineers state that cotton grows prolifically on these lands without any additional fertilizer, indicating the ease with which the potash is made available.

#### COTTRELL PROCESS INSTALLATIONS IN CEMENT PLANTS

In all of the cases mentioned above, potash is volatilized and must be recovered from the gases. The Cottrell process has met with excellent success in this phase of potash recovery problems. The field of application which has been developed the farthest is in the recovery of potash from cement kiln gases. Several plants are now in successful operation and at the present time a considerable tonnage is being obtained in this manner. Other plants are under construction and the outlook for a much larger tonnage is very favorable. In the August 21 issue (1918) of *The American Fertilizer*, published at Philadelphia, Penn., John J. Porter, General Manager of the Security Cement and Lime Company of Hagerstown, Maryland, in an article entitled "The Recovery of Potash as a By-Product in the Manufacture of Portland Cement," gives a great deal of valuable information upon this problem. The following is quoted from that article. "Estimating Potash Recovery." For the benefit of those who may wish to figure on their own conditions, I give the following method of calculating the probable recovery of potash:

- Let A equal per cent potash in raw mix.  
 B equal per cent potash in clinker.  
 C equal per cent liberation =  $600A - 380B \div 600A$ .  
 F equal lbs. of potash recombinced per bbl. clinker = 0.7 to 1.5.

depending on fuel consumption and per cent ash in coal.

Let P equal per cent potash precipitated in treaters.

Assume 600 lb. of raw mix actually used to make 1 bbl. of clinker,

then—Lb. of potash entering kilns per barrel of clinker equals 600A.

Lb. of potash volatilized in kilns per barrel clinker equals 600 AC.

Lb. of water soluble potash entering treaters per barrel clinker equals 600 AC-F.

Lbs. of water soluble potash collected in treaters per barrel clinker equals  $(600AC-F) \times P$ .

The cost of collecting potash at Security is now running about as follows:

|                                                                  | Per Unit of Potash |
|------------------------------------------------------------------|--------------------|
| Collection, including labor, power, repairs and laboratory ..... | \$0.14             |
| Packing and shipping .....                                       | 0.08               |

Total operating cost exclusive of depreciation, royalty and salt addition.....\$0.22

The cost of the salt addition is about \$0.25 per unit of potash, but this is not a necessary element of cost and can be omitted whenever price conditions become such as to give an unsatisfactory margin of profits.

The article then goes on to show that from a 3000 barrel cement plant, the operating profit per annum on the potash alone comes to about \$458,000, the raw mix having 0.75 per cent of potash. The article is quite complete and those interested are referred to it for further details. The Bureau of Soils published the results of their survey of cement plants. The data given indicates that this industry can be counted on to

furnish 80,000 to 100,000 tons of potash annually. By using materials which are higher in potash content, such as feldspar, sercite or slate in part, the yield of potash can be materially increased. The additional cost for raw material should be weighed against the greater financial return from the plant operation as a whole and not allow first cost per ton of material to govern. The utilization of existing cement kilns and equipment for the manufacture of cement as a by-product, placing special emphasis on the potash yield and profits therefrom, should be urged by all citizens, and this should be more emphatically urged for the recovery of potash from blast furnace gases. The feat of obtaining all of our potash from existing industries by recovering the by-products will be typically American and worthy of our "Yankee ingenuity." The by-product method will enable us to compete with potash from any other source, and the Kaiser's vain boasts that all countries will be compelled to submit to his will because they must have his potash, shall receive their proper answer.

#### POTASH PROSPECTS IN THE IRON INDUSTRY

Referring again to the iron industry and its relation to the potash question, it should be pointed out that in the Alabama district there is an abundance of excellent coal, labor is plentiful and cheap, and the climatic conditions are such that the district may be considered an all year one as far as operating is concerned. Then, when it is realized that there is immediately at hand an enormous tonnage of high grade iron ore which carries such a large potash content and that the South produces our cotton and therefore is the large consumer of potash and thus provides a large market within a few miles, the economic importance of this situation can be better appreciated. Other iron ores contain potash, some of which may justify recovery plants, and we should be on the lookout for such materials, keeping in mind that our goal is to obtain our potash as a by-product at such a cost as will enable us to ignore Germany forever and thus make the dreams of the American chemist and engineer come true.

The South produces pig iron cheaper than any other district in normal times. In fact their furnaces must do this in order to stay in the market. The South does not yet consume as much iron and steel products as its population justifies and therefore their iron must carry a high freight charge if it is shipped North to the larger markets. The manufacture of cast iron pipe has, however, grown to a large industry. In the future more and more iron and steel will be consumed locally as it is evident that the South is coming into its own very rapidly. The additional profit which can be obtained from the potash will be of great assistance in keeping their iron furnaces in blast when the market sags. The South has a very fortunate combination of labor, raw materials, climate and a large and near fertilizer market. In France and in Great Britain the Governments have taken an active interest in the possibilities along the lines herein pointed out. It has been reported that investigations extending over a period of three years have shown that Great Britain can produce enough potash to satisfy all her requirements.

## Potash from Alunite in Utah

BY JOHN W. HORNSEY

THE arbitrary action taken by the German Government some years ago in forcing Americans who had purchased interests in German potash works to join the German Potash Syndicate and the lack of tact displayed by those who handled the situation for Germany, created so much ill feeling that all together it brought about the determination upon the part of the United States Government and of American buyers to find some source of potash other than the German, and plans were thereupon made for both governmental and independent searches. Fortunately for this country, when war was declared in 1914 these searches had developed a large amount of valuable data.

Both the Geological Survey and the Bureau of Soils were granted appropriations and began active work, which has proved to be of considerable value. However, the independent investigators made a somewhat more comprehensive survey without going quite so exhaustively into details, except where it seemed reasonably certain that a commercially workable supply would be found.

All probable sources of supply were investigated, including feldspar, kelp, desert lakes, leucite and alunite. It was evident from the start that potash could not be produced profitably at anti-war prices from certain of these materials without the production and sale of by-products, and for some of these by-products there was only a limited market. In other cases a somewhat more careful study of the subject showed that potash was unquestionably the by-product. This work has, however, definitely resulted in the development of a permanent potash industry in this country, and I say permanent advisedly, for some of the plants will, undoubtedly, be able to continue after the war.

### ALUNITE

Many centuries ago alunite was mined in Smyrna and for about 400 years in Italy and was used for the production of potash alum. When the search for potash began in this country, it was felt that a deposit of alunite might be found and that it might be used as a source of potash rather than potash alum. About this time such a deposit was discovered in southern Utah, a few miles from Marysvale. Later it seemed that it would be necessary to discover some means of refining the alumina before potash could be produced in competition with Germany. However, early in 1915 when the price of potash had risen to what seemed impossible figures, Mr. Howard F. Chappell and his associates of the Mineral Products Corporation decided to build a plant, and this has been in continuous and successful operation for three years, except for two shut-downs of one or two months each caused by fires. They are now producing and shipping about 600 tons of sulphate per month, and the product is considerably better than 90 per cent pure.

Several formulas are given by various authorities to indicate the chemical composition of alunite a double sulphate of potassium and aluminium, of which the following is representative:

The above formula appears to be nearly correct, i.e., for the alunite now being worked at the town of Alunite near Marysvale. Several methods have been proposed for the treatment of an ore of this character for the production of potash, but probably the simplest one is that employed in this plant where the ore is calcined at approximately 1000 deg. C. This drives off water of crystallization and sulphuric acid, leaving water soluble potassium sulphate and alumina. Upon leaching and evaporation of the resulting solution, potash is recovered as sulphate with a very small percentage of soda and some infinitely fine alumina which has passed through the filter cloths.

The alunite from the Mineral Products Corporation's mine is of a distinctly crystalline nature and from 96 to 97 per cent pure alunite. There are other large deposits nearby but they are more nearly amorphous in appearance and carry more silica, which seems to interfere with the calcination and also with the subsequent refining of the alumina.

The alumina residue, containing any silica present in the ore, is now discarded; but it is planned later to refine and use it. It has been discovered that the silica content may be reduced to less than one-half of one per cent by calcination with producer gas instead of pulverized coal and separation of the alumina from the silica by flotation. The average silica content of the ore used by Mr. Chappell's company is  $3\frac{1}{2}$  per cent. The loss on ignition is approximately 40 per cent, and the raw ore contains an average of approximately 10 per cent of  $\text{K}_2\text{O}$ , or  $18\frac{1}{2}$  per cent of  $\text{K}_2\text{SO}_4$ . The plant is operated profitably, and by reason of improvements and refinements which have gradually been developed, will, it is believed, be able to compete with Germany after the war.

### PINTADOS DEPOSIT IN CHILI

About sixty miles from the coast and directly on the railroad in northern Chili, is a deposit which while it cannot be correctly called a lake the result is essentially the same, and contains several hundred thousands of tons of workable potash in the form of a crystal body directly on the surface, averaging about 18 in. deep and covering many thousands of acres. The average analysis will show about 5 per cent of  $\text{K}_2\text{O}$ . This potash upon leaching and crystallization can be recovered as the muriate, or, if mixed with the raw material from which sodium nitrate is made and which immediately joins this deposit, can be recovered as the nitrate.

While this deposit is not in the United States, it is 1000 miles nearer to New York by water than California and is located where labor and other conditions are so favorable as to offset the high price of fuel. The climate is better than at some points in our western deserts and the country has a stable government. Revolutions are unknown and there has been less change in their constitution and general governmental methods during the past century than in the United States, England, France, or any other large country.

### GREAT SALT LAKE

This is a body of brine that has not gone nearly so far in the process of desiccation as Searles Lake. It has, however, for some time been looked upon as a possible source of potash. In fact, the Diamond Match Co. has had a plant in operation there for the past two or

three years, and has recently doubled its output. The Virginia Caroline Chemical Company in coöperation with the Inland Crystal Salt Company of Salt Lake City has also built a plant. However, the composition of the brine of the Lake is such that a very large amount of evaporation is necessary before the bitter liquors are sufficiently saturated with potash to make them workable. The primary evaporation is effected in open air, clay-lined ponds, during which considerable quantities of sodium chloride are thrown out. The bitter liquor remaining is then worked up for the separation of potash which is effected by evaporation, heating and cooling; and depends upon the varying relative solubilities of the different salts. The principle difficulty encountered is to bring about a satisfactory separation of magnesium chloride.

## Potash from Iron Ores and Fluxes

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—Your editorial in regard to the recovery of by-product potash from blast furnaces is very timely. Only a few days ago I heard an expert connected with the War Industries Board express the view that the infant potash industry of this country may prove to be of an importance far above that represented by our immediate needs for potash, in connection with the negotiations for peace. The idea is that Germany will probably attempt to use her supposed monopoly of potash as a club to secure better terms, and certainly many utterances of her public men can be cited to bear out this theory. As it happens, there is in the August 1 number of the *Journal of Industrial & Engineering Chemistry*, page 665, a translation of an article from the *Deutsche Wirtschafts-Zeitung* of January 15, 1918, on "The German Potash Industry" in which the same idea is clearly expressed. In view of this probability, an established potash industry in this country might easily have a value not to be reckoned in dollars and cents if used to call the German bluff.

The recovery of potash in connection with the manufacture of Portland cement is going ahead very rapidly and largely because of the successful experience of the Security Cement & Lime Company. There are at the present time fourteen potash-recovery plants either in operation or in course of construction. Of these, eight are using or will use the Cottrell system, while six will use various other systems of collection.

The industry is still in its infancy and great advances in technical efficiency are possible. At Security we have already succeeded in increasing our percentage of potash volatilized (and thereby made available for collection) from about 40 to about 75 per cent. It is undoubtedly possible to carry this liberation even higher and it is also possible to greatly increase the efficiency of the collection apparatus. Even on the basis of the present state of the art, however, the cement industry is capable of furnishing approximately 100,000 tons of  $K_2O$  per annum or about one-third of the total requirements of the country.

Data do not exist for the calculation of the possibilities of the iron industry as a source of potash, but as you have pointed out, they are probably very great, and in some respects the proposition is more attractive than in the case of the cement industry. In the blast

furnace the volume of gases to be treated is much less per ton of material passing through the furnace than in the case of the cement kiln so that on the basis of equal potash content, the size of the investment in collecting apparatus would be less.

As I was at one time connected with the blast-furnace industry, I have been much interested in the possibilities of potash collection there ever since the success of our cement installation had been demonstrated. In coöperation with Mr. O. M. Stull of Buena Vista, Virginia, I have worked out a potash balance for one blast furnace and, so far as I know, these are the first data of the sort to be presented, with the exception of Wysor's excellent work published in the 1917 *Transactions of the A. I. M. E.*

|                             | Tons    | Lb.                                    | Per cent | $K_2O$ (Lb. of Total) | Per cent |

| Slag.....                   | 1,444   | $\times 2,240 \times 0.500 \div 100 =$ | 16,172   | 32.9                  | 32.9     |
| Volatilized.....            |         |                                        | 17,543   | 35.7                  | 35.7     |
|                             |         |                                        | 31,639   | 64.3                  | 64.3     |

\*The percentage of potash found in the pig iron is so small as to raise the question whether it is not due to analytical error. However, the net result as to potash liberation is, in any event, only slightly affected.

This balance is based on a two-weeks' run, all materials except the slag being weighed and all analyses made in duplicate by a chemist experienced in potash determination. The weight of the slag was calculated. It will be noted that the percentage of potash volatilized from the furnace and which might, therefore, be recovered was 64.3 per cent of that entering the furnace, and amounted to 31,639 lb. in the two-weeks' period. As this furnace was working on a lean mixture with large slag volume and a fairly siliceous slag, it is probable that this figure represents somewhat less than the average liberation to be expected in blast-furnace practice.

These analyses show that the brown ores of Virginia are relatively low in potash; some published analyses in old reports of the U. S. Geological Survey show that this is also true of the majority of the Lake Superior ores. The Clinton red ores of the South are also low in potash.

The grey hematites of Eastern Alabama are probably the principal deposits of high-potash iron ores available in this country. The quantity of these ores has been estimated at 50,000,000 tons and upwards and the potash content ranges all the way from 1 to 3 per cent and over. It will probably average about 1.5 per cent. A little calculation will show that the possibilities for potash production from these ores are very attractive indeed. Aside from potash content, the analysis of the ore is very similar to the average brown ore of Alabama, and it has been used successfully at various times in blast furnaces in this district. An attempt is now being made to work out a project for the use of these ores involving the recovery of their potash content and it is to be hoped that it will meet with the success which it deserves.

### The Exhibit of the Ceramic Section

TIME was when "Jena" and "Royal Berlin" were names to conjure with, and "Made in Berlin" was a sign of excellence which we now know can be achieved by other than Teuton ceramists. A visit to the ceramic section of the Exposition will convince one that the declaration of ceramic independence has been written for the United States, and that our brands of glass and porcelain ware are now free from the stigma of foreign antecedents.

The achievement constitutes one of the romances of the war. Prior to 1914 it was so easy to secure good laboratory glass and porcelain from Germany that nobody seriously considered domestic production. Schools and colleges got their supplies duty-free, and commercial organizations did not have to pay high prices. So thorough was our dependence that the industry had to be built from the bottom when war disturbed our customary imports.

Of course the country was not without potters and potteries, but their direct experience with laboratory porcelain was not extensive. Also we had glass works, but our brands of laboratory glassware had been regarded as inferior. The abstract of the census of manufactures for 1914 makes no mention of laboratory porcelain; nor does chemical glassware achieve the distinction that is given to nest eggs.

The problem was not too difficult for American manufacturers, however, and to-day's result is laboratory ware of excellence. This issue of CHEMICAL & METALLURGICAL ENGINEERING is a complete story of American ceramic independence. The various authors emphasize the possibilities of American raw materials and demonstrate the satisfaction rendered by the finished products. Their remarks should arouse a feeling of pride in every American chemist.

### American Clays and Ceramics

THE clay products industry is perhaps the most ancient and honorable of the chemical allies. Vases and urns of a considerable degree of fineness are constantly being found in the burial mounds of the prehistoric inhabitants of our hemisphere. The art appears to have originated in Asia and the fact that the aborigines of America knew it well indicates that there is some kinship between the Indians of Columbus and the oriental peoples. Upon the landing of the colonists in America, ship traffic was such that bricks and other clay products offered the most convenient form of return ballast, so that buildings along our coast from

Portland to Galveston were built of English brick. However, as our pioneers penetrated farther and farther into the forest, imported bricks became a burden, and with the pottery of the Ohio Indians showing what could be done, it was only natural that the ceramic industry should eventually be started. However, the colonial potter had been schooled to European methods and recipes, so that while he freed us of imported bricks, he subjugated us to foreign clays wherever the product would stand the freight.

With the recent interruption in ocean traffic and German imports, a much needed punch has been put into our ceramic industries. Foreign clays and clay products were stopped with a bump. The wheels of the industries began to turn faster than ever before. Ceramists had to get busy and contribute their share. How admirably the requirements have been met are exemplified at the Fourth National Exposition of Chemical Industries. From bricks to aeroplane engine spark plugs is a long trip, but the journey has been made at a finish pace that will break the world's records for speed.

The one great need for the acquisition of perfection in ceramics is the proper understanding of the science involved in the art. Chemical and physical properties cannot be studied independently. The requirements of the scientists in this field are so great and the technology so rich, that the American Ceramic Society is going to issue a journal. That greater progress is to be expected by this infusion of modern science into ancient ceramics goes without question from the results of the short period just past. American chemical porcelain ware will go down into the history of our industries with honors.

## Economics in the Works

**S**OME time ago we were called upon to examine into a long established industry. We were expected to admire, but we found nothing to praise. The leaders were men of eminence, many of whom had made comfortable fortunes while some had achieved great wealth. Wages were high even in normal times, and we were expected to show amazement and wonder and delight at the city's pride. But we did not. There was neither coöperation nor coördination nor research to be observed. There were wastes that might have been decreased at nearly every turn and there were opportunities to reduce the time factor in many processes, but the owners had no apparent interest in discovering them. Whether they believed in research or not they certainly did not encourage it. They were willing to let some other fellow pay for experiments.

We are trying very hard to do our share in the development of chemical statistics, but statistics require records, and the unprogressive manufacturer is conservative and declares that he is unwilling to publish his business secrets. In most cases he would be ashamed to have them known. From the census we can gather the production of raw materials and the gross products manufactured from them, but these estimated yields are incomplete and they constitute at best but *ex post facto* information. We can only compute the economic standing of an industrial establishment when we con-

sider the theoretical yields and compare them with its actual achievements.

It may not be profitable to publish such figures, but it is remarkably unprofitable not to know them. And yet how many manufacturers today know the relation of the performance of their works to the theoretical yields? We venture the opinion that the percentage is small, although this information is a proper accompaniment to cost-accounting, because it serves as a constant check upon neglect. Too often we have known manufacturers, who through ignorance and neglect were unable to attain the same yields as the more enlightened foreign competitors, to appeal to Congress for tariff duties to protect them against their own shortcomings. We venture the opinion that no manufacturer should have standing before the Tariff Commission who is unwilling to confess his yields.

If the waste is known to be excessive, where is it? How much of it is unnecessary? If it is in the materials, in which one is the fault, and what is the fault? How may it be corrected? Again, if the laboratory control is fair and the loss is unwarranted by good practice, the chances are that there is defect in supervision, because the workmen are not adequately trained. But that again is usually less the fault of the laborer than it is of the master, whose business it is to educate his men rather than to instruct them.

A man who is educated to perform his work knows the reason for every act. He becomes the master of the materials entrusted to his charge, and he knows what to do. If he is a good man he will want to learn, and he is less likely to make mistakes. The one who is instructed merely knows, for instance, that he must turn a cock off or on when something happens, and that is all he ever does know. The same attention is not to be expected from him as from the man who knows why he should do it and just what is happening. It is very important that this kind of education proceed apace in this country. In Germany, before the war, it was easy enough to have a specialized chemist in technical charge of every process. The workmen were organized under pseudo-military discipline and the Herr Doktor would utter *das Kommando* which the men would obey.

We cannot afford to maintain so large a professional faculty for the same amount of work in America. We doubt also if many American employers could stand that number of German chemists in their establishments, and American chemists won't work for the price. Moreover, we know very well that American workmen would not endure the *Kommandos* of the German chemists. We must, therefore, to come out even, educate our workmen to do a good part of that which was done by the German *Betriebschemiker*. This takes time and patience and good-will.

Chemical manufacture in America requires therefore first of all, familiarity with and practice of research. It demands also constant study of actual as compared with theoretical yields. It needs more intensive study of processes and consequently a broader understanding of their nature by the technical director of American works than was needed by a man in the same position in Germany, because the American technical manager cannot have as many graduated assistants. And provision must be made for the intelligent education of the workmen. Mere instruction is not enough.

## Sidelights on the Exposition

Among the whirling and moving exhibits is that of the Raymond Impact Pulverizer Co. of Chicago which shows a full-sized automatic pulverizer and  $\frac{1}{2}$ -size mill, pulverizer and separator, all in operation. To carry conviction they separate hominy and cork-dust and the exhaust fan from their cork-dust pulverizer blows right into the exhibit without messing things up. Each piece of apparatus is provided with windows to show what is happening inside. That is a good plan, whenever it is possible.

\* \* \*

One of the chemical colonels who visited the exposition told of a cootie-killing device that has been proposed which does the work by means of high-frequency currents. Tests that have been made thus far prove very favorable. One difficulty which the authorities met in their preliminary work was to have the desired number of cooties in one place for the necessary animal experimentation and to avoid, at the same time, any untoward distribution of them. The situation has been met by a good and patriotic man, too advanced in years for the draft, who is doing his bit by providing his own and proper person as host for the lively *pediculi*. These are herded, if we may use the term, within rings which are plastered upon the body of the pioneer in specialized patriotism and covered over to provide a safe enclosure. Within the enclosure and also underneath the cover there is laid a small piece of felt to allow the mother birds to lay their eggs under conditions which approximate, as nearly as possible, her normal home, but without the usual accompaniment of freedom. Whether the eggs endure the lightning flashes which follow in the interest of research we do not know, but parents as well as bachelors and spinsters (if there be any) and the growing youth of the species are said to succumb immediately.

We hope the anti-vivisection societies will not feel a call to protect the lives of these animals. Indeed, we fear their genial host might refuse to function if the vigorous old ladies who champion the cause of man's fellow beings of the animal world, were to insist that to the host's guests there be given life, liberty and the privilege to pursue happiness. St. Francis of Assisi is said to have referred to cooties as "Little Pearls of Righteousness," put in view of the fact that modern churchmen hold to the relative rather than the specific value of tradition, we are of the opinion that this animal experimentation may be carried on without sin.

\* \* \*

Among the exhibits that attract a crowd by the display of things in motion is that of an automatic sprinkler device for extinguishing fires. Owing to an excess of zeal, however, many of those who stop to look and listen are driven away again. The good people overbid the market, as it were. A large glass chamber is provided which is water-tight and at the top of which is fixed a sprinkler-head. For realistic demonstration of what happens in case of fire an automatic alarm bell is adjusted in the usual manner to the riser so that when a sprinkler begins to operate the alarm is sounded. At intervals, therefore, there comes forth from this gong an infernal, nerve-racking din which

is designed to induce any man who enjoys the use of his ears to jump into his clothes. The customary police rules against nakedness prevail at the Palace so that everybody present is clothed. The whang of this fire-gong therefore very nearly, but fortunately not quite, makes everybody jump out of his clothes and take to the windows. To the optimistic temperament there is always occasion for thanks. We rejoice that our booth is not adjoining.

\* \* \*

The Newport Chemical Works, Inc., of Milwaukee, show phenol, of course, for they make not less than 125 tons a day of it, we are informed. They have also an impressive list of coal-tar intermediates of which the following bear the bull's-eye mark: Dinitro-oxydiphenylamine, ortho anisidine, chromotropic acid, alphanaphthylamine and dianisidine. Guaiacol, c.p. in crystals and liquid is offered for pharmaceutical purposes. Then, firmly insisting that Milwaukee is on the map of the United States and probably also because they have a considerable number of intermediates full handy, they have gone into dyes and display a couple of dozen direct, acid and sulphur colors.

\* \* \*

At the exhibition of the Swenson Evaporator Company we were informed that they have just completed a caustic-soda reclaiming outfit for the U. S. Government Explosives Plant C at Nitro, W. Va., of very large capacity. It includes evaporators, disc evaporators, incinerators, leaching battery and other apparatus which required over 30 car-loads for shipment.

\* \* \*

Major Leo F. Goodwin, formerly of the College of the City of New York but now of Canada, was pretty well smashed up by the Huns, but he is still in the ring. As he sat in the booth of CHEMICAL & METALLURGICAL ENGINEERING yesterday, reading our daily issue he suddenly pointed to a line, looked up and asked "Who wrote that?" The line he indicated was that in which we offered free and clear, with no patent rights claimed, the suggestion that tellurium dyes might be made to take the place of sulphur colors. The guilty man was present and acknowledged his invention. "Have you ever worked with tellurium compounds?" asked the major. The guilty man admitted that he hadn't. "Well, you never would have put that idea into the minds of aspiring young chemists if you had!" he continued. Then he related from his own bitter experience something of the habits of tellurium, when it starts out in chemical society and begins to make combinations. It displays, he declared, an odoriferous character that reminded him of garlic that had committed suicide. It seems as agreeable and as strong as the mercaptans, and even more enduring. He imagined a beautiful, golden-haired child all arrayed in a pretty new tellurium-blue dress, obviously by a mother with atrophied olfactory organs. And the major, who is fond of children, could imagine no other course of action for the distressed father to pursue than to throw the child out of the window upon the rubbish heap and to make a dash for the North Pole.

Poor tellurium is evidently without friends. We lately reported the indifference of the copper refiners to

it and now comes this learned professor who displays a distinct antagonism.

\* \* \*

The E. I. duPont de Nemours Company shows a great variety of things. Among the novelties is a new rough pyroxyline finish called "crystalac" that may be applied to any hard surface. It is very effective and handsome on glass. They have entered the field in making bronze powder which is displayed in various stages of manufacture. Another thing is dip-colors for electric lights which are applied to finished incandescent bulbs. Artificial limbs are exhibited, made of *papier mache* with a pyroxyline finish. The samples are pink or flesh color, but we have no doubt but that they could easily produce a whole series of chocolate and horse-chestnut hues to meet even the approbation of the art critic of the *Chicago Defender*. Last year they gave away samples of a household cement which this year is going strong without the need of free samples. Under the trade name of "pontoklene" they show a preparation to remove road-tar from automobiles. In the fabrikoid department they have coming along and ready to introduce, but not yet shown, a kind of hospital sheeting that is an improvement on rubber sheets. From the Harrison Works they have of course a great line of paints, and at the dyestuff end are shown about fifty intermediates and some twenty-five direct, basic, acid, chrome and sulphur dyes. This company is engaged in the manufacture of so many different kinds of chemical products that any discussion of the scope of their activities sounds like a poem by Walt Whitman.

\* \* \*

The coal-tar tree is shown in many manifestations. The National Aniline & Chemical Co. has a large number of bottles arranged in the form of a pyramid with tar at the apex; on the shelf below are the crudes and on the two shelves below this is a comprehensive array of complicated intermediates. Dr. Derrick, the head of the National company's great research laboratory at Buffalo was present as we passed by and we congratulated him on his vast progeny of research. "It was co-operation that made them possible," he replied, "and believe me, some of them were hard to bring up. In fact, some of them were as full of tricks as the wildest boy that ever wanted to shoot Indians."

The National Company conceives the bull's-eye to show that the products have been made in America and by them for the first time from all American materials. They have 169 subjects so marked and very few of them have been made by anybody else in this country before out of German or any other kind of intermediates. Another feature of their show is that nothing is displayed which the company cannot deliver. Some products which are very much desired are on hand in appreciable quantity but they will neither be shown or offered until regular production is established in the works. We were glad to observe one sample of dye and colored yarn of the indanthrene type. That is a good sign. We have been whistling for these colors for a long time.

\* \* \*

The sign of the bull's-eye, which means made in America for the first time since the war began, is

differently construed. Some exhibitors hold it to indicate articles made for the first time with all American materials while others construe it to mean that articles so designated have never been made in this country before without reference to the origins of materials. Others again seem to hold that anything which they themselves make and now show as their own product for the first time is entitled to a bull's-eye. And others, having distinct novelties, do not attach it at all. The sign would have more value if there had been made a clearer definition of its purpose; however, bull's-eyes have always been hard to hit at the first shot.

\* \* \*

A guest at the expositiion who is in a quandary how to produce certain materials fast enough to meet his contracts owing to the labor shortage, said that he would know exactly what to do with 40,000 Turks, which is a question said to be bothering General Allenby at the present time.

\* \* \*

Sometimes we think we know what is going on if we read the journals and the advertisements and go to the meetings of the chemical societies and visit the Chemists' Club, but we make no pretensions to the eagle eye that sees everything. For instance, there's Mr. Floyd J. Metzger who was associate professor of industrial chemistry at Columbia University until a year ago last February. He gave up academic distinction to engage in work for the Air Reduction Co.—the Claude process people who make liquid air and sell oxygen; it is a large concern as everybody knows. It stands to reason that they must have some nitrogen on their hands; lots of nitrogen.

Right there is where Mr. Metzger has been at work and at the Exposition the Air Reduction Co. has a single booth on the third floor. They show a considerable array of synthetic sodium cyanide, made of that boiled nitrogen, and we are told that the technology has been brought up to the theory:

This reaction has been somewhat of a teaser for a long time, but we are assured that the theoretical yields of ammonia and sodium formate are achieved. Now in addition to the cyanide and formate of sodium there are displayed the following products of their New Jersey works: formic acid and seven formic esters, up to amyl formate; sodium ferrocyanide; aqua ammonia and sulphate, chloride, nitrate and carbonate of ammonium together with *Paris* and Turnbull's blues. The name *Paris* is given to this otherwise Prussian blue on the ground that, being a synthetic product it lacks the usual livers and lights and consequently deserves a better name. The works are still small but are operating at maximum capacity.

We confess that we feel like apologizing. With nitrogen fixation going on, right across the table, so to speak, and we missing it, we feel we need some of Col. Sellers' Celebrated Eye Wash to quicken our sight. It makes us feel like the boy who went to the Sunday School entertainment and missed the circus. If Mr. Metzger were one of those silent fellows that keeps off in a corner by himself we should not take it so to heart, but he isn't; he is a good mixer.

## Recent Developments in Ceramics\*

### Increased Demand for Silica Brick—Replacement of German Clays—Development of Porcelain and Chemical Stoneware Industries—Success in Optical Glass Manufacture

By A. V. BLEININGER

ONE of the most important functions of the ceramic industries is the supply of refractories for the metallurgical operations of the country, steam power-plants, byproduct coke oven, gas plants, glass works, and many other purposes too numerous to enumerate here. The demand for these products has been enormous and has been met by the refractories industries in a very satisfactory manner. Although at times the need of No. 1 fire-bricks has been greater than the production, such a condition does not exist at the present time, owing to the expansion of this branch of the industry. In many instances the extraordinary demand was caused in part by the unwillingness of consumers to use anything but No. 1 refractories even for purposes where lower-grade products would serve equally well. Fire-bricks of the lower refractory grades are available in abundance, especially since a considerable number of face and building-brick plants have taken up the production of this type of ware. One of the urgent needs in this connection is the establishment of a classification and specification of the several grades of clay refractories. This task is being undertaken at the present time by the War Industries Board. The work of standardizing the shapes of fire-brick has already been accomplished in a satisfactory manner.

#### COKE OVENS INCREASE DEMAND FOR SILICA BRICK

The demand for silica bricks has been greatly increased through the development of the byproduct coke oven. Meeting this demand involves not only large quantity production of these refractories, but high quality as well. It is necessary that the transformation of the quartz to cristobalite be largely completed as indicated by the lowering of the specific gravity to a value of not more than 2.38 and that the product possess good mechanical strength, corresponding to an average modulus of rupture of about 500 pounds per square inch. These requirements are exacting and may not always be met in bricks made from silica rock other than quartzite. Certain materials, like chert and flint, transform to cristobalite more rapidly than quartzite but do not yield as strong a product. Sandstones usually transform more slowly and likewise tend to give inferior strength.

The manufacture of silica refractories is certain to expand still more, both in the eastern states and in the middle west. If the war continues for any considerable period, additional emergency production in connection with the erection of new coke-oven plants will certainly be necessary.

Difficulties have been met in supplying the basic magnesite refractories from the available American

materials. This has been due to the nature of our magnesite, which differs from the Austrian ore in being very low in iron oxide and sometimes higher in lime. This makes it necessary to add the iron synthetically, a procedure which adds to the cost of production, since it requires intimate blending and grinding of the mixture and a higher calcination temperature than is needed with the European raw material. In addition the magnesite must be transported across the continent from California or Washington. The latter state produces at the present time large quantities of magnesite quite low in lime and the quality of the material is of a character which is making it possible to reduce operations to a uniform practice.

It has been found possible also to replace magnesite bricks in certain operations by bauxite refractories. The production of magnesia spinal refractories of the composition  $MgO \cdot Al_2O_3$  has made a beginning and it is not unlikely that for many purposes it will prove a very desirable material. There has naturally been a shortage of chromite refractories, even though the quantities really needed are small. This has been overcome by the use of thinner partings and in many cases by doing away with this refractory entirely without apparently any serious effects.

#### SUPERIORITY OF CEYLON GRAPHITE

Much has been said on the question of graphite crucibles. The graphite problem is undoubtedly the more important one in this connection. It is a difficult matter to replace Ceylon graphite altogether with the domestic mineral. In the first place the greater density of the imported material, 2.25, which imparts to it the characteristic resistance to oxidation, its foliated structure, and the low ash content of the best grades combine to make it extremely satisfactory for the purpose of crucible making. This graphite can be bonded together with a comparatively small amount of clay, since the surface factor per unit weight is smaller than for that of any other kind of graphite.

This point may be illustrated by the volumes occupied by the same weight of several types of graphite. Thus, 100 grams of ground Ceylon graphite after thorough shaking occupies a volume of 90.7 c.c., Canadian graphite 119.6 c.c., and Alabama graphite 152.0 c.c. In other words, it would be impossible to make graphite mixtures of maximum carbon content from the two American materials. Since they offer a much larger surface the amount of clay used must be greater. From this it follows that the ultimate density and thermal conductivity are certain to be lower.

To what extent American flake graphite can be admixed with the Ceylon graphite remains to be seen. The writer has seen mixtures in which the flake added

\*By permission of the Director of the Bureau of Standards. Read at the meeting of the American Ceramic Society, New York, September 26, 1918.

amounted to 20 per cent of the total graphite content and gave fair foundry results. It might be possible, however, to perfect processes which will enable the crucible maker to employ larger percentages of domestic graphite, and at the same time secure practically the same results as with Ceylon graphite. On the other hand, there is no reason why a large quantity of domestic graphite should not be used in the making of stoppers and similar articles. The comparison made between the Ceylon and flake graphite is, of course, relative, and refers to crucible value obtained per dollar at the present time. If for some reason this country could no longer obtain Ceylon graphite, the production of metal certainly would not be diminished in any way, as we could get along very well with flake and amorphous graphite, furnace carbon, and coke.

#### GERMAN CLAYS SUCCESSFULLY REPLACED

The lack of the German Klingenberg clay for crucible making is not as serious a matter as has been thought. It has been shown conclusively that it can be replaced both by English and American ball clays.

Similarly, the German Gross Almerode clay used in the making of glass pots has been replaced by American clays and synthetic mixtures in a very satisfactory manner. In fact, it is quite probable that the new techniques now being developed will yield results superior to those formerly obtained with the use of imported clay. The shaking up caused by the war will, in the end, be of distinct service to the glass refractories industry. At the same time, the glass industry will gain in pot service through the realization that the control of the heating up process of the pots in the arches is essential in preventing loss.

Special clay refractories have been developed also with reference to improved thermal insulation, including materials highly refractory, light in weight, and possessed of good insulating qualities. The saving in fuel consumption and weight through the use of such products is bound to be considerable.

#### DEVELOPMENT OF PORCELAIN INDUSTRY A NATIONAL DUTY

The manufacture of hard-fire, true porcelain has received a powerful impetus through the war. Three plants are already operating successfully on the production of chemical porcelain, and are making rapid strides with respect to quality. The manufacture on a large scale of hard porcelain tableware is to be begun in the very near future. It is very fortunate that the pioneers in this work have realized the importance of putting their production on a firm basis with reference to foreign competition. By the use of automatic machinery, mechanical dryers and tunnel kilns, they will be enabled to meet foreign competitors on equal terms. The plants now in course of construction excel all European potteries in the elimination of unnecessary labor cost, and expenditure of fuel. The development of a hard-fire porcelain industry is, indeed, a national duty. It would be preposterous and humiliating to contemplate any further dependance on Germany and Austria for these products. By establishing this industry we shall be in position to seek the South American markets to which we have a fair right.

The demand for ordinary tableware at the present

time is greater than has ever been known before and difficulty is being experienced in supplying the requirements of the Army and Navy and at the same time those of the country. The simpler shapes such as cups and mugs are now being produced by the one-fire process, which incidentally results in an appreciable saving of fuel.

#### NEW PORCELAINS SHOW HIGH ELECTRICAL RESISTANCE

Porcelains for special purposes have been developed successfully. Thus, the national Bureau of Standards has introduced the manufacture of the refractory Marquardt porcelain, essentially sillimanite, formerly produced by the Royal Porcelain Manufactory at Berlin and used so largely for pyrometer tubes and similar articles. Likewise, we have succeeded in making porcelains possessing remarkably high electrical resistance at elevated temperatures. Several of the bodies produced in the Pittsburgh laboratory of the Bureau of Standards showed a resistance of one megohm per cubic centimeter at 780 deg. C. and at the same time a coefficient of thermal expansion of only  $3.81 \times 10.6$  per deg. C. between the temperature range of 30 to 400 deg. C.

The same materials showed none of the variations in thermal expansion common to most porcelains, the coefficient remaining practically constant throughout the range of 30 to 520 deg. C. It is evident that such properties, coupled with good mechanical strength, are essential for such uses as aeroplane spark plugs. There is every reason to believe that the principles thus worked out will greatly assist in producing special grades of electrical porcelain for use under severe conditions. These developments have been assisted greatly through the use of the petrographic microscope in the study of porcelain structures.

#### FURTHER DEVELOPMENTS IN PORCELAIN EXPECTED

The manufacture of electrical porcelain is undergoing improvements at a more rapid rate than ever before in the history of this particular industry. The methods of preparation are more thorough, the details of shaping are being studied more carefully, the drying process is being controlled with greater accuracy, and the methods of testing developed toward more exact differentiation as to quality. The casting process is finding application to an increasing extent. Further developments are to be expected with reference to the composition and firing of electrical porcelain, based on more recent studies on the subject of the function of feldspar as an electrolyte and the volume changes induced by the transformation of quartz to its several crystalline modifications.

Considerable work is being done also with regard to the complete survey of the resources of the country in kaolins and ball clays for use in the ceramic and paper industries, through the agencies of the Association of State Geologists, the Bureau of Mines, the U. S. Geological Survey, the American Ceramic Society, and the Bureau of Standards. It is believed that this survey will enable us to take stock of our resources with the final object of making ourselves independent of any foreign sources. A considerable number of new clay deposits have been located within the past two years, to

say nothing of glass, sand and other ceramic raw materials.

#### CHEMICAL STONEWARE INDUSTRY OF VITAL IMPORTANCE

One of the clay industries vital in the prosecution of the war is the manufacture of chemical stoneware. The production of this type of ware requires particular skill, owing to the complicated designs, large size and the necessity of the tight fitting of the pieces. But few realize the magnitude of the task which confronted this industry, especially when handicapped by shortage in labor, fuel and other necessities. It is very gratifying, indeed, to be able to say that the stoneware manufacturers have met the situation so well and have been able to supply the needs of the chemical industries. This statement applies equally to the manufacturers of acid-proof, enameled cast-iron and sheet-steel products which have played an important role in recent chemical developments.

Another industry having a direct bearing upon war work is that engaged in the manufacture of abrasives and grinding wheels. The rapid growth of this branch of manufacture and its technical development are characteristic of America. Its work has been done with such quiet efficiency and it has met the demands of the present conditions so promptly that but few realize the magnitude and importance of its accomplishments. Research has played a large part in this development and to the utilization of scientific facts we owe the highly specialized grinding tools made available for large production, as well as for the most delicate processes, such as the grinding of optical lenses.

The industries engaged in the production of ceramic structural materials have naturally been hard hit by the decrease in building activities and by the fuel orders. The manufacturers of building bricks, hollow tiles, sewer pipe, paving bricks, terra cotta, floor and wall tile etc. are endeavoring to hold together their organizations. In districts where war activity prevails the plants are operating to capacity; in others new branches of manufacture have been taken up, such as the production of refractories, crucibles, and certain specialties for war use. But even under such conditions interesting developments are taking place. Much attention is being given to the question of fuel economy through more rapid firing and the utilization of waste heat. New applications of clay are being found such as the use of crushed vesicular vitrified brick material as an aggregate for concrete, having the advantage of light weight, low thermal conductivity, and constancy of volume when heated.

#### OPTICAL, SIGNAL AND CHEMICAL GLASSWARE

With reference to the glass industry the three most interesting developments are those relating to the optical, colored (signal), and the resistant or chemical glasses. When it is realized that at the beginning of the war but little optical glass was being produced in the United States, the rapid development of the art presents an inspiring example. The necessity of war brought together the manufacturers on the one hand and scientific and technical organizations like the Geophysical Laboratory of the Carnegie Institute and the Bureau of Standards on the other.

Although some of the manufacturers had brought their furnace practice to a very satisfactory state it was not realized fully that the raw materials must be practically free from iron, sulphur, chlorine, and other impurities. Likewise, methods for the rapid examination of the glass were lacking so the frequently poor glass was brought to the grinding and polishing rooms of the optical shops; very often, too, good product was by chance rejected. The necessity of temperature measurement and control was not fully realized and the method of stirring had not been brought to a satisfactory development. At the same time the commercial glass pots were the source of much grief due to their high iron content, which discolored the glass in the absence of decolorizers which are not allowable and their failure to resist the corrosive action of the flint and barium glasses. These things have been overcome to a very large extent.

#### RAPID PROGRESS IN PRODUCING GOOD GLASS

Through the use of sand of great purity and constant checking of the composition of the other constituents, the primary difficulties have been removed. The composition of the glasses has been correlated with the optical properties, the index of refraction, the dispersion value, and the light absorption. Time-temperature schedules have been worked out for the melting and cooling periods and satisfactory stirring machines designed. Rapid inspection even of the glass in lump form is now possible by the use of immersion methods and examination with mono-chromatic light in addition to the examination through the polished edges of blocks.

The pot problem has been solved through the use of white burning clays like the kaolins and even more satisfactorily by the production of semi or true porcelain pots. Containers of the latter type are now being made in several works and have proved eminently useful. In fact, it has been possible to melt in such pots dense barium crown glasses which have proved exceedingly destructive to the ordinary types of refractory materials.

#### ESSENTIALS OF OPTICAL GLASS MANUFACTURE MASTERED

The annealing process is being studied by a number of workers, and some interesting information has already been obtained. It might be said then that in the United States we have mastered the essentials of the production of optical glass, and about seven types are being manufactured commercially. Problems dealing with the cutting down of the losses of certain optical phenomena etc., of course, still remain; it is to be expected that continued progress will be made in this art.

It is a source of pleasure to note also the fact that scientific and technical researches dealing with the technology of silicates are being continued at the present time, even though they have more or less bearing upon conditions brought about by the war. We are mastering more and more the control of the class of dispersed systems represented by clays floated in water, their drying behavior, and the changes which they undergo upon vitrification and fusion by resorting to the methods of the scientific investigator.

In this brief survey it has not been possible to empha-

size some of the more important technical advances, nor was it permissible at this time to dwell upon certain developments, such as a new rôle played by clay in chemistry, but it is hoped that this hasty contribution might afford some conception as to the activities in the ceramic industries.

Bureau of Standards.

## Chemical Glassware

By E. C. SULLIVAN

MORE chemical glassware is made in this country to-day than was imported before the outbreak of the war, when we depended upon foreign makers for practically our entire supply. The quality is excellent. The Bureau of Standards reports that all of the five brands of American-made beakers and flasks which it tested are equal or superior to the highest grade foreign glass and that one American glass is far superior in the important property of resistance to mechanical shock.

From Table I compiled from the Bureau of Standards report,<sup>1</sup> it is apparent that on an average four of the five brands of American flasks and three of the five brands of American beakers were less soluble than the German in the nine reagents used.

TABLE I—COMPARISON OF FOREIGN AND DOMESTIC GLASSES

|              | H <sub>2</sub> O | NH <sub>3</sub> | (NH <sub>4</sub> ) <sub>2</sub> S<br>& NH <sub>4</sub> Cl | Acids | Na <sub>2</sub> HPO <sub>4</sub> | Na <sub>2</sub> CO <sub>3</sub> | K <sub>2</sub> CO <sub>3</sub> | NaOH | KOH | Total |
|--------------|------------------|-----------------|-----------------------------------------------------------|-------|----------------------------------|---------------------------------|--------------------------------|------|-----|-------|
| Beakers..... | 4                | 4               | 2                                                         | 5     | 5                                | 3                               | 3                              | 5    | 4   | 23    |
| Flasks.....  | 4                | 4               | 5                                                         | 5     | 4                                | 3                               | 2                              | 5    | 3   | 35    |

(The figures indicate the number of brands of American glassware found to be less dissolved in the respective reagents than the brand of imported ware formerly regarded as the best on the market.)

### SUPERIORITY OF AMERICAN BEAKERS

The American beaker shows superiority over the foreign in twenty-five cases and equality in four cases (one with water, two with ammonia, one with acid) while the American flask is superior in thirty-five cases and equal in one case (with caustic potash). This difference between the comparative showing of the beaker and that of the flask is almost too great to be accidental and seems to indicate that the foreign flask is more soluble than the foreign beaker.

Another class of laboratory ware, in which resistance to sudden temperature change and to attack of reagents is of less importance and which includes such shapes as desiccators, cylinders, bell-jars etc. has been of slower development in this country but these articles are now being made here in reasonably satisfactory quantity and quality.

Suitable tubing for working before the lamp in the manufacture of such apparatus as cannot be blown or pressed directly in the glass-factory is now produced also, and gratifying progress has been made in the organization of lamp-working<sup>2</sup> establishments for thus manipulating the tubing into the more complicated shapes.

<sup>1</sup>Technologic Paper of the Bureau of Standards, No. 107, "Comparative Tests of Chemical Glassware," by Percy H. Walker and F. W. Smith (1918).

<sup>2</sup>In the glass trade the "glass-blower" works molten glass from the melting-pot or tank, blowing it into bottles, beakers, tubing, etc.; as a rule he knows nothing of the fabrication of apparatus from tubing in the flame, which is the function of the "lamp-worker."

### SPECIAL GLASS FOR ARMY MEDICAL DEPARTMENT

Referring more specifically to what has been accomplished in chemical glassware since this country entered the war, in the first line would come probably glassware furnished the U. S. Army Medical Department for bacteriological purposes. This glass, which is reported to be of quality far ahead of any ever imported, was absolutely essential in the immunization of the troops against typhoid fever, an immunization the results of which have been record-breaking and for which the U. S. Army Medical Department cannot be given too high credit. Very large quantities of high-grade chemical glass of special shapes have been supplied to ammunition manufacturers also.

In view of the fact that the highest priced American-made beakers and flasks are selling at practically the duty-paid pre-war price of the highest grade imported ware, although the latter has since been advanced in price twice, it may be of interest to consider for a moment in the light of tariff protection the circumstances which led to the establishment of the chemical glassware industry in this country.

At a Tariff Commission hearing on glass held in Pittsburgh in January, 1918, Commissioner W. S. Cudertson remarked, "This case of chemical glassware is an excellent example of a war disturbance. Here is an industry not in existence in this country before the war; the war has raised an artificial barrier against competition from abroad and we have growing up in this country a new industry."

### REASONS FOR ENTERING THE FIELD

The factors which had weight in determining American manufacturers finally to enter a field from which they had hitherto held aloof were as follows:

1. Sentiment. Undoubtedly patriotic motives and the strong appeal made by chemists and supply houses to glassmakers for relief from the threatening shortage were of some influence.
2. Higher returns. The fact that without foreign competition the full duty-paid price could be asked on all sales, to educational institutions as well as to others.
3. Assured market. There was no slow ousting of the foreign competitor from his established position to face, as would have been the case had the American goods been protected only, for instance, by an extension of the duty to include importations for educational institutions.

If No. 2 was the determining factor it follows that duty-free importation by educational institutions has prevented earlier development of this industry in America. If duty-free importations are 50 per cent of the total and if the tariff is 45 per cent *ad valorem*, then for every dollar saved to the educational institutions about \$4.50 of American money has been paid the foreign glass manufacturer which, with a domestic industry developed, would have remained here.

On the other hand, if, as is more likely, No. 3 was the factor of most influence, it follows that a prohibitive barrier, such as interruption of commerce or a very high tariff, may be effective in enabling an industry to get a foothold without causing any increase in price to the consumer.

# Recent Developments in the Cement Industry

## Conversion of a Peace Industry to the Purposes of War—Economies Effected in Fuel and Labor, and Recovery of Potash

By RICHARD K. MEADE

THE cement industry can hardly be said to have profited by the war, although the price of its product is very much higher now than it was several years ago. This increase in price, however, has been met to a large extent by the present high wages paid labor and the cost of fuel and supplies. During the last year, also, the production of cement has been very much curtailed, due to the difficulty of procuring the men, fuel and repair parts necessary to operate the plants at anything like their full capacity.

The cement industry is essentially a peace industry. Its product goes largely to the building trades, for the making of roads and pavements, in municipal improvements, in the development of water powers etc., all of which work has very largely stopped during the past year. As with the metal industries, the output of the mills is now going largely into work of national importance which is approved by the War Industries Board, probably 90 per cent. of the cement shipped today being destined for such use.

The construction work engendered by the war is not of a type in which large quantities of cement are used. The temporary character of the greater portion of this has made the use of concrete unnecessary and the speed with which construction must be pushed has made other building materials more acceptable.

There have been few compensating features to this situation. Both the technical and popular press has given much space to the concrete ship. While most concrete engineers are firm believers in the importance of this type of vessel for emergency purposes, its successful development would not mean any large increase in the use of cement. Any one of several large producers of cement could, by working his plant at full capacity, produce cement enough in one year to duplicate the entire present ship tonnage of the allied nations; and almost any works could produce enough cement in one day's time to build a ship of the size of the "Faith," the first large concrete ship.

### FUEL AND LABOR LARGEST ITEMS IN COST

In probably none of the great non-metallic industries does fuel play such an important part as in the manufacture of cement. In normal times, the cement mills of the country use between 8,000,000 and 10,000,000 tons of coal; or almost half as much coal is brought into the plant as there is cement carried out of it. The high price of coal and the difficulty of obtaining this have, therefore, been felt very keenly in the cement industry.

The largest item in the manufacture of cement, in spite of the automatic handling of the materials at all stages of the process, is labor. Under ordinary condi-

tions these two items, fuel and labor, make up 80 per cent. of the cost of manufacturing a barrel of cement. The value of the raw materials plays very little part in the cost of manufactures as these consist principally of limestone and shale or clay, which are usually obtained by quarrying from practically inexhaustible sources at the plant itself. Transportation difficulties have also fallen heavily on the cement manufacturer as even a small mill requires from 15 to 20 box cars per day to carry its product away.

### ECONOMIES IN FUEL, LABOR AND POTASH

So much for the business side of the industry. The principal technical developments have been along the line of saving labor and the recovery of potash and heat from the waste gases of the rotary kilns. Improvements, however, owing to the high cost and difficulty of doing construction work, have been confined to only a few plants, and with the vast majority of works the war has made no difference except, as in all other industries, in rendering operation extremely difficult.

Viewed from the chemical standpoint, the most interesting occurrence has been the collection of potash from the waste gases of the rotary kiln. As far back as 1904, the writer, at a meeting of the Association of American Portland Cement Manufacturers, called attention to the fact that approximately half of the potash in the raw materials was volatilized in burning the cement and that the crust which collects on the walls of the kiln stack and has to be removed at intervals contains a considerable percentage of potassium sulphate. No attempts were made to recover the potash from the kiln gases prior to the war, however, and owing to its low percentage of potash I believe that none of the crust was sold for this constituent.

### SOLVING THE DUST NUISANCE

There has always been objection raised by some of those living near cement mills to the fine dust which is carried out of the kiln stacks and which deposits in the vicinity. While it is extremely doubtful if this dust does any harm to vegetation and certainly is not injurious to health, at the same time it has proved a bone of contention between the cement works and its neighbors. In Southern California particularly, suits brought by the orange growers against the cement plants resulted in injunctions restraining the cement plants from operating without taking care of the dust. The two plants in Southern California, the Riverside Portland Cement Co. at Riverside, and the California Portland Cement Co. at Colton, immediately installed dust-collecting systems. Dr. Cottrell had just worked

out his electrical precipitation method and this was installed at the Riverside plant. The California Portland Cement Co. installed a system of large dry settling chambers followed by washing chambers for treating their gases which was devised by their manager, Mr. T. J. Fleming.

It was soon noticed that the dust recovered by the Cottrell process contained an appreciable amount of

to his directors that they install the apparatus, which they did. This plant has been unusually successful and has been collecting daily from 20 to 25 tons of dust containing from 8 to 15 per cent water-soluble potash, which is sold directly to the fertilizer manufacturers.

When the apparatus was put in operation here, a peculiar thing was noticed, that whereas at Riverside practically all of the potash present in the dust was

water-soluble, at Security a considerable portion was not water-soluble. The explanation for this is that at Riverside the kilns are heated with oil while at Security pulverized coal is used, and it is believed that in some manner the potash recombines with the coal ash to form a silicate. This silicate of potash, however, can be dissolved with dilute acid or it can be made soluble by leaching the dust with water under pressure in an autoclave.

By adding salt to the raw materials, the volatilization of potash from these can be very materially increased. Messrs. Huber and Reath recommend and have patented the use of

calcium fluoride for a similar purpose. It was also discovered at Security that by the use of salt the recombination of the potash with the coal ash could be lessened to a considerable extent. It has been found, however, that where salt or calcium fluoride is employed the efficiency of the treater is decreased, and that while the volatilization is increased there is a proportionately larger quantity of potash not caught by the treater. In order to collect the potash so lost, a supplementary water-film electrical treater has been developed at the Security plant through which the gases are passed after leaving the dry treater. This is now said to be working satisfactorily.

The Cottrell dry treater, as most chemists know, consists of a large number of sheet-iron tubes through the center of which wires are suspended. These two form the electrodes, the gases passing up through the tube, the dust being deposited on the surface. In the water-film treater, the wires are employed but are located between two walls of concrete over the surfaces of which a thin sheet of water is allowed to flow and between which the gases pass. This film of water is a conductor of electricity and acts as does the surface of the tube in the pipe treater. The discharge between the wire and the water-film carries the potash to the latter where the water dissolves it. The same water is circulated over and over again, the solid matter being allowed to settle out; the solution thus gradually builds up in potash. When of the desired concentration it is drawn off, any solids left in suspension are filtered off, the liquor is evaporated, and the potash salts obtained by crystallization.

We have mentioned the precipitation of the dust at the plant of the California Portland Cement Co. by the use of dry settling chambers followed by water

FIG. 1.—POTASH-RECOVERY PLANT, SANTA CRUZ PORTLAND CEMENT CO.  
(FANS NOT RUNNING)

potash. No serious attempts were made, however, to sell this dust until the outbreak of the war, when it became a marketable product.

A little later on, Messrs. Huber and Reath, chemists of the Riverside Portland Cement Co., developed a process for extracting potash salts from this dust. The process is quite fully described in *METALLURGICAL & CHEMICAL ENGINEERING* of June 15, 1917, and consists briefly in leaching the dust with hot water, separating the solution from the insoluble matter by means of a rotary filter, evaporating the filtrate to the point of saturation and crystallizing the potash out of this in shallow tanks. The product obtained runs from 35 to 40 per cent potash and consists very largely of potassium and sodium sulphate with some sulphur in a lower state of oxidation.

With the outbreak of the war, the crust which collects inside of the kiln stacks became valuable and large quantities of this have been sold by the cement manufacturers in the past three years. The dust runs between 8 and 12 per cent potash. The quantity of the potash so recovered, however, is very small when compared with the total potash liberated in the kiln.

#### FIRST PLANT PRIMARILY FOR POTASH RECOVERY

The first Portland cement company actually to install apparatus with a view to collecting potash was the Security Cement & Lime Co., Security, Md. Mr. J. J. Porter, manager of this company, was a visitor at the National Exposition of Chemical Industry in the fall of 1915. While there he saw the Cottrell process in operation in a small way and was impressed with the possibilities of collecting potash by this process. He made a trip to the Riverside plant, saw the apparatus there at work, came home and recommended

sprays. It was quite natural that the attention of this company should also have been attracted to the possibility of obtaining potash, and a process for such recovery has been worked out by Mr. W. C. Hanna, chief chemist of this company.

#### WET SYSTEMS OF RECOVERY

In this system, too, the water circulates through the spray system over and over again and gradually gets stronger and stronger in potash. When of the desired strength, a certain portion of this liquor is pumped over into a tank where it is used to leach the dust which collects in the dry chamber. The dust is then separated from the solution by means of an Oliver filter. The former is returned to the kiln and the potash solution is evaporated in open pans. These are located on top of the flue leading the hot gases from the kilns to the treater, all of the heat necessary being furnished by the waste gases. As this flue slopes, each pan is set somewhat lower than the preceding one and the liquor to be evaporated flows from the top pan down through the whole series. The potash is shoveled out of the lower pan and is either dried on the casing of one of the fans and placed in sacks for shipment or else sent to storage in the damp state. This plant is now producing between 3000 and 4000 pounds of potash salts per day, containing approximately 40 per cent potash.

The Santa Cruz Portland Cement Co., Devonport, Cal., has installed a system developed by Mr. F. H. Davis, manager, Mr. Fred Davis, superintendent, Mr. L. T. Bachman, chief chemist, and their associates. The collection here is effected by means of water, the distinctive feature of the installation being the use of excelsior beds through which the gases are made to pass after being scrubbed in a tower with water. The gases are first washed in the scrubbing tower by means of sprays and are then passed up through the excelsior beds which are 2 ft. and 6 ft. thick respectively. The solutions flow into a large sump, where solid matter settles, and are recirculated. The mud and liquor are pumped by means of diaphragm pumps to the tank of an Oliver filter, which separates the solids from the liquor. The former is burned to cement and the liquor is evaporated to dryness in a rotary kiln, which happened to be a spare unit in the plant and hence could be utilized for this purpose to advantage. The yield at this plant is about 4 pounds of potash salt per barrel of cement. The salts usually run about 36 per cent potash, principally as sulphate.

#### SPRAY TREATERS IN UTAH PLANTS

Messrs. Huber, Trainor and Fisher of the Riverside Portland Cement Co. have designed a spray treater which they are now installing at two plants, that of the Ogden Portland Cement Co. at Ogden, Utah, and the Utah Portland Cement Co. of Salt Lake City, Utah. This consists of two large brick chambers, the first of which is called the "saturater" and the second the "condenser." Each chamber is divided into four or six compartments by means of brick partition walls so arranged that the gases pass alternately from bottom to top of the large chambers. Sprays are located in the top and the corners of each compartment. In their course, the gases become saturated with water vapor in the "saturater" and then this vapor is condensed in

the second or "collector" chamber. The water is circulated over and over again and the potash collected as at Riverside.

Still another system for collecting the potash is employed by the Southwestern Portland Cement Co. at their plant at Victorville, Cal., which was worked out by Mr. J. G. Dean, chemical engineer of the company.<sup>1</sup>

FIG. 2.—POTASH-RECOVERY APPARATUS, SOUTHWESTERN PORTLAND CEMENT CO.

The wet process of cement manufacture is employed at this plant. The gases issuing from the kiln, carrying from 30 to 40 per cent of water, pass through a condenser where this vapor condenses, probably around the dust and potash particles, and collects with the latter in the condenser tubes. The potash, of course, goes into solution and the dust remains in suspension. The condensed liquor is used as the cooling medium while the hot gases passing through the tubes are made to evaporate this solution. This is brought about by maintaining a vacuum above the latter, so that the apparatus is really a vacuum evaporator in which the kiln gases take the place of the steam ordinarily used. The solutions are concentrated in this evaporator to a density of about 1.1 and the evaporation is finished in an open-top steam evaporator provided with a salt box in which the potash salt collects and from which it is shoveled out when the box is full, allowed to dry in open air, ground and packed.

#### TWO POUNDS POTASH VOLATILIZED PER BARREL OF CEMENT

The quantity of potash volatilized at the average cement plant amounts to about 2 pounds of potash ( $K_2O$ ) per barrel of cement; or on the normal output of one hundred million barrels annually, the total volatilized in this country would be about 100,000 tons. Apparatus now available will catch from 60 to 80 per cent of this in water-soluble form. In 1918, 13,582 tons of potash material, equivalent to 1621 tons of  $K_2O$  and valued at \$700,523, was sold by the cement industry. In 1918 the production probably will be equivalent to

<sup>1</sup>"Wet Process for Extracting Potash from Cement Waste," By J. G. Dean, this Journal, Sept. 26, 1918.

about 3500 tons of  $K_2O$  valued at one million and a half dollars. When all of the plants now under construction are operating at full capacity the output will be equivalent to 10,000 tons of  $K_2O$  annually valued at present prices at about four and a quarter million dollars. There is a possibility of very materially increasing this quantity of potash by substituting for the shale and clay now used as raw materials certain materials of similar composition rich in potash, such as feldspar, sericite, certain shales found in Georgia and other states, leucite etc.

It may be of interest to note that largely through the efforts of Mr. R. C. Haff, chief chemist of the Security Cement & Lime Co., a rapid and very accurate volumetric method for determining potash in cement materials, dust etc. has been worked out. This method is a modification of the cobaltinitrite precipitation followed by titration with permanganate, as used in the laboratories of most of the eastern cement companies and has been found, as now modified, to compare very favorably with the platonic chloride method.

#### APPLICATION OF WASTE HEAT FROM KILNS

That the heat in the waste gases from the rotary kiln operating on the dry process represents about two-thirds of that supplied by the fuel used to heat the kiln has long been known, and various attempts have been made to utilize this heat in boilers. The first attempts were made at the plant of the Nazareth Cement Co. some twenty years ago and a little later at the plant of the Cayuga Lake Cement Co. Neither of these installations was entirely successful and both attempts were abandoned. Within the last few years, however, efforts to utilize the waste heat in boilers have been successful. The feature which seems to have made these latter installations successful where the earlier ones failed is the fact that the gases were led through the boilers at a fairly high velocity.

The method of using the gases for the generation of steam consists in drawing these through the boiler by means of a fan. The boilers are located as near the end of the kiln as possible and any dust which collects on the boiler tubes is blown off by means of steam.

In the newer installations it is found possible to produce practically all of the power necessary to operate the plant from the kiln gases. It is estimated that the installation of boilers after the kilns at all the cement plants in the country would save approximately one-third of the coal now employed in the cement industry, or about 2,500,000 tons of coal annually. Practically all cement manufacturers realize the vast saving which could be effected by the installation of waste-heat boilers. Unfortunately, however, just at this time it is almost an impossibility to obtain the boilers; moreover, the cost of installation under present conditions is such that the average cement plant does not find it easy to finance the undertaking.

It may be said that the waste-heat boilers and potash precipitation apparatus work very well together, as the flucs, dampers, fans etc. for one installation will serve for the other; and since the size of the dust treaters is proportional to the volume of the gases to be cleaned, the boilers will cool and hence reduce the volume of the gases enough to permit of very much smaller treaters being used. Such combined potash and boiler installa-

tions are now in operation at the plants of the Dexter Portland Cement Co., Nazareth, Pa., and the Alpha Portland Cement Co., Cementon, N. Y.

Baltimore, Md.

## The Annealing of Glass\*

GLASS has to be annealed to remove any strains set up in it by improper mechanical or thermal treatment, and the presence and development of strains is revealed by passing a beam of polarised light through the glass. Although this optical method of examination has long been applied by physicists and manufacturers of optical glass, it is hardly known to the average glass manufacturer. The Department of Glass Technology of the University of Sheffield has therefore investigated the annealing of glass and the relationship between the composition of a glass and the suitable conditions for its annealing with the special object of facilitating the optical examination and of devising simpler mechanical methods of testing. "Notes on the Annealing of Glass," giving an account of these investigations, were communicated to a recent meeting of the Society of Glass Technology, by Messrs. Solomon English, M.Sc., and W. E. S. Turner, D.Sc.; the latter is in charge of the Department of Glass Technology at Sheffield. Though these notes were only offered as introductory, the detail given are of considerable interest.

#### INFLUENCE OF MOLECULAR STRAINS ON POLARIZED LIGHT

In a polarization apparatus the beam of light, polarized by passing through the first Nicol prism, is stopped by the second Nicol, when the two are crossed. On introducing a cylinder of glass, strained with fair regularity, between the two Nicols, some light will pass and a system of colored rings will be seen, the number of rings increasing with the intensity of the strain. The strain can be removed again by proper annealing of the glass, and the glass manufacturer is mainly interested in three things: the "upper" annealing temperature at which the strain can rapidly be removed without risk of deforming the glass; the "lower" temperature at which the strain can be removed at a slow rate; and the quickest rate of cooling which may safely be used for cooling between the upper and lower temperatures without setting up new strains. For their optical examination, English and Turner use cylinders, 3 cm. in length, with plane polished ends which are placed in a tubular electric furnace. Such a specimen, if severely strained, will show seven rings and the central black cross. As the temperature rises, the rings broaden and seem to chase one another out of the field of view; the number of rings thus diminishes, they become indistinct and vanish, leaving only the black cross, which finally occupies the whole field; that is to say, the field is uniformly dark when all the strain has been removed. In the experiments the times were determined at different temperatures which were wanted both (a) for clearing the field of rings and (b) for making the field quite dark, and it was observed that a temperature difference of a few degrees in a lehr or other annealing oven made a large difference in the time required. Thus the results were:

\*Republished from *Engineering*, Vol. CVI, Aug. 9, 1918.

| Temperature,<br>Deg. C. | (a) Time Required | (b)                        |
|-------------------------|-------------------|----------------------------|
| 500                     | 20 5 hrs.         |                            |
| 550                     | 50 min.           | Not black after 0.5 hours. |
| 600                     | 20 min.           | 4 5 hours.                 |
| 625                     | ..                | 18 minutes.                |
| 650                     | ..                | 10 minutes.                |

The glass of these experiments was of a fairly high "upper" temperature. In a lead glass, the upper temperature of which was only 450 deg. C., the (a) were 35 min., 20 min., and the (b) more than 6.5 hours, 130 min., 2 min. at the temperatures of 400 deg., 425 deg., 450 deg. C.

Rapid annealing requires softening of the glass, and it was therefore investigated whether the rate of bending of heated sample rods and the rate of annealing would run parallel with one another. For this purpose a rod of the glass mounted axially in a horizontal tubular furnace, was fixed at the one projecting end, while the other free end played over a vertical scale; the sagging of the free end was measured. The general shapes of these curves proved the assumption just stated, and that glass anneals rapidly when the softening begins. Messrs. Beatson, Clarke and Co., of Rotherham, continued these tests. A test rod, 1 yard long,  $\frac{1}{4}$  in. in diameter, was drawn out from the metal in question, and supported at its center on a brick, which was placed on the pan carrying bottles down the lehr. Arriving at the cool end, the ends of the rod were each found to have sunk by  $\frac{1}{2}$  in.; in that case the bottles were found to be strained on examination. When the glass remained in the hot zone for about 15 minutes and was satisfactory, the ends of the rod had sunk by about 3 in.; with prolonged heating at higher temperature the bending became excessive.

#### RATES OF COOLING VARY WITH CHEMICAL COMPOSITION

As regards the rate of cooling, English and Turner find that the cooling rate should neither be uniform throughout the period, nor first be accelerated and then slowed down again, or *vice versa*, but that the glass may, first, *i.e.*, just below the annealing temperature, be cooled rapidly; as the glass stiffens the rate of cooling should be very slow until the glass has become rigid, when the rate may again be accelerated. Thus the rate of cooling should be variable. Three stages would probably prove sufficient. In the first stage, glass of an upper annealing temperature of 585 deg. or 590 deg. C. may be cooled at the rate of 25 deg. per hour down to 500 deg. C.; during the next stage 500 deg. to 400 deg. C., even a slow rate of 9 deg. per hour gave rise to some strains; in the cooling-off stage the rate could once more be raised. Each stage would correspond to a different section of the lehr, and the question is, whether the annealing oven can economically be so constructed as to admit of varying the rates of cooling. When only one variety of glass is made, the mechanical difficulties would not be great; but when glassware of different compositions and different thicknesses are to be annealed together, which is the common practice, the fastest rate of passage will have to be adopted, it is pointed out, even if this rate be that of the slowest glass to be annealed. How much the chemical composition influences these rates is shown by the data of the paper. A glass containing 30 per cent of lead oxide had to be annealed at 450 deg. C.; it could

be cooled down to 400 deg. at the rate of 120 deg. per hour, but between 400 deg. and 300 deg. the rate should not exceed 50 deg. per hour, while below 300 deg. the high rate of 300 deg. per hour was permissible. These figures concern a rod 7 mm. in thickness. For electric lamp globes this glass could be cooled at the rate of 12 deg. per hour down to 300 deg. C., and then be allowed to cool off in the open air. Wine glasses could be treated in similar ways. Lime-alkali glasses had to be cooled slowly, at 10 deg. per hour, from 550 deg. down to 320 deg., the further cooling being completed in 3 hours. Boric acid glasses (with 23 per cent of  $B_2O_3$ ) proved surprisingly difficult to anneal at 570 deg.; as borax acts as flux and diminishes the expansion coefficient of a glass, one might expect ready annealing; but the important factor is the rate at which the viscosity varies throughout the temperature range in which annealing can occur. Chemical glassware containing 64 per cent of silica, 10 per cent of alumina, 7 per cent each of barium and calcium oxides, and 11.5 per cent of soda and potash, proved the most troublesome; between 500 deg. and 400 deg. this glass has to be cooled so slowly that Messrs. English and Turner had so far failed to get an 8-mm. rod through this region without some signs of strain.

#### The Absent "C" in Germany

One of the peculiarities of the German language is the general absence of the third letter of the alphabet. As the ancient Huns became civilized, put on clothing and began to make a book of words, they thought that they could best teutonize the language of their neighbors across the Rhine by leaving out the "c's." Thus they changed cheese to käse, Caesar to Kaiser, cement to zement, came to kam, and so on. However, they made one great oversight and forgot to put the "k" in the right place in chemiker. Perhaps some scribe is to blame for this error but the theft could be made no more evident even by the bulging of the tunic.

Why the ancient U-boat navigator's vorvaters had this great aversion for "c" has only recently been discovered. You see the English controlled the seas and hence the German Huns couldn't use them.

Le Chatelier and Bogitch have adapted the Brinell ball test to the measurement of the hardness of bricks, by laying thereon a piece of thin lead foil, 30 mm. square and 0.05 mm. thick, previously blackened by treatment with hydrogen sulphide in a faintly acid solution, dried, and smeared with vaseline, most of which is wiped off again so that a matt surface is produced. The ball polishes the surface of the metal with which it comes in contact and this facilitates accurate measurement of the diameter of the depression. Tests with lead and copper showed that the foil does not interfere with the size of the depression produced. The ball used is 17.5 mm. diameter and is applied for 1 min. under a pressure of 500 kilos. The results are much more concordant than those obtained in determining the crushing strength of bricks. The test is useful in controlling the manufacture of bricks as it will show notable differences in the hardness of different parts of the same brick, due to irregularities in making or burning, or to an insufficient taper in the mould.—*Compt. Rend.*

# The Chemical Stoneware Industry and the War

Phenomenal Expansion of the American Industry—American Manufacturer Has Nothing to Learn from Europe—Standardization Desirable for Some Shapes—Domestic Materials Equal to Imported

By PERCY C. KINGSBURY

Chief Engineer, General Ceramics Co., New York City

THE OUTPUT of structural materials and equipment for chemical purposes has naturally received a remarkable stimulus from the phenomenal expansion that has taken place in the chemical and allied industries during the past few years. Obviously the extraordinary progress that has been made in the manufacture of chemical products has been dependent in a very large measure on increased production of the necessary plant and apparatus. It has also been dependent upon the efforts of American manufacturers to furnish equipment which had previously been imported from Europe. The success of most of these efforts is a gratifying tribute to the research departments of our large corporations and scientific institutions, the effect of which in rendering independent our future industrial development is almost impossible to exaggerate.

A result of this wonderful development has been that many minor industries in this country have assumed a position of the most vital importance. Of these the manufacture of chemical stoneware is one of the most remarkable.

Manufacturers were and are still unable to keep up with the sudden increase in demand for their products, this being due to no lack of initiative on their part as will be appreciated when some of the facts concerning this material and its production are taken into consideration.

A parallel condition was found among both groups of the belligerent countries in Europe. It has been intimated in the British technical journals that in England at the outbreak of the war, owing to the lack of suitable chemical stoneware equipment to remove noxious fumes, the workers in munition plants suffered severely in health. France, which depended almost entirely on Germany and Austria for her chemical stoneware requirements, has been obliged to turn over some of her world-famous china and pottery plants to the manufacture of this product.

Germany evidently realized the importance of this industry to the production of war materials. I have been informed that notwithstanding her need for men she exempted from military service the employees of the chemical stoneware plants in the country. She has also made a number of serious, but happily abortive attempts to tie up the production of chemical stoneware in this country.

## SERVICE REQUIREMENTS OF CHEMICAL STONEWARE

Before discussing the advance that has been made in the manufacture of chemical stoneware in this country during the war, let us decide what this ware is intended to comprise.

If the innumerable purposes for which chemical stoneware is used are considered, it is obvious that no one

body could possess all the necessary physical and chemical properties required.

This ware covers an entire range of ceramic bodies from the open structure bodies of a firebrick nature, used in the manufacture of vessels subjected to considerable range in temperature, to the dense bodies of a porcelain like nature used for electrolytic work. Within this wide range of products special bodies have to be devised to meet special conditions.

For instance, the low tensile strength of chemical stoneware as compared with metals is somewhat of a handicap that we can only minimize but not entirely overcome by skilful design. It has, therefore, been necessary to prepare mechanically strong bodies for use in the manufacture of such apparatus as acid eggs and impellers for pumps and exhausters that are subjected to considerable tensile stress.

The remarkable results that have been achieved along these lines are indicated by a statement by F. A. Whitaker at the last meeting of the American Institute of Chemical Engineers in which he gave comparative figures of the tensile strengths of English and German stoneware and the bodies that have been developed in this country during the past ten years.

## AMERICAN MANUFACTURERS EQUAL EUROPEAN

In every other respect also, the exigencies of the war have demonstrated that the American chemical stoneware manufacturer has nothing to learn from the European manufacturer.

At the Chemical Exposition is exhibited one of the largest pieces of stoneware (although not the largest) that has ever been produced in this country. It is doubtful if there are more than two other plants in the world that could manufacture a vessel of this size.

The design of stoneware mechanical appliances and machinery is complicated by the very high shrinkage that takes place during manufacture, which may vary from 8 per cent linear shrinkage or less for some clay bodies, to 16 per cent or more for others. This means that the greatest possible care must be exercised if strains in the finished ware are to be avoided.

In this field we have reason to be well satisfied with the progress that has been made during the war. There is now no stoneware mechanical appliance produced in Europe that cannot and has not been duplicated here. In a number of instances the design has been improved and further progress along these lines is under consideration.

An effort has recently been made in England to standardize such chemical stoneware shapes as is possible. This work was initiated by some of the smaller manufacturers and does not appear to be making much

headway, presumably through lack of encouragement from the larger manufacturers.

#### DESIRABILITY OF STANDARDIZATION IN SHAPES

That there is urgent need, however, for such standardization, only those who have to cater to the capricious demands of some of the users of this ware can fully appreciate. Taking as a simple example ordinary bell and spigot piping, some users demand a bell only 1½ in. deep while others using the same size pipe under substantially the same conditions insist on a depth of 5½ in. We find the same condition throughout our entire production. This means for the manufacturer the accumulation of an enormous stock of molds and the consequent increase in his overhead expenses, and for the user extra expense and delay which could well be avoided.

In view of the enormous increase in the use of chemical stoneware, particularly in connection with the manufacture of toxic gases and explosives, a review of the useful properties as well as of the limitations of this product may be of value.

The great advantage of chemical stoneware is its resistance to practically all chemicals met with in industrial work. In common with all silicious products, it is acted upon by hydrofluoric acid at all temperatures. It is also acted upon to some extent by phosphoric acid at temperatures above that at which chemical stoneware is ordinarily employed. Strong caustic alkalis, especially when hot, also have action upon it. When the conditions in regard to temperature and strength of solution are not too severe, the life of chemical stoneware when used for alkaline solutions is sufficient to justify the use of the ware for this purpose, but strictly speaking, alkali-proof chemical stoneware is a misnomer.

#### THE NATURE AND PURPOSE OF THE GLAZE

There appears to be a popular impression that the acid-proof qualities of chemical stoneware are dependent upon the glazed surface. The glazing should be for the purpose only of adding to the smoothness and appearance of the surface but should not be depended upon to improve the acid-proof qualities of the body. However, as a good deal of nonsense as well as deliberate misrepresentation has appeared on this subject, a few words might not be out of place.

The two methods employed are the application of a prepared glaze by means of a spray or brush, and salt glazing. The prepared glazes may be considered as clay bodies having a lower fusing point than the ware to which they are applied. At the temperature at which the ware begins to vitrify, the glaze melts forming a more or less homogeneous coating over the surface of the stoneware. This is nothing more nor less than a veneer or enamel and has all the disadvantages of enamelled ware in that the slightest scratch or pinhole, or other imperfection will allow the acid to penetrate to the surface beneath; and if the body is not properly vitrified and thoroughly acid-proof the action of the acid will ultimately result in the peeling off of the glaze. Cracking or cracking of this glazed surface is a natural and obvious result of subjecting such ware to changes in temperature.

Salt glazing is carried out by throwing common salt into the fire as the maximum temperature of firing is

reached. The salt volatilizes and the vapor reaches every part of the kiln where it is decomposed, the salt forming a double silicate with the alumina and other bases in the clay body, while dense fumes of hydrochloric acid gas pass up the chimney. A salt glaze is, therefore, a true glass intermolecularly combined with the body and one, therefore, which cannot craze nor peel. Moreover, as a salt glaze will not form on a surface that is imperfectly vitrified, this form of glaze is guarantee of the proper vitrification of the body.

#### DOMESTIC MATERIALS EQUAL TO IMPORTED

The idea, carefully fostered by those interested, of the superiority of imported raw materials, has been exploded in so far as it relates to the manufacture of chemical stoneware.

There was a time when we (I refer to the company with which I am associated) imported about 80 per cent of our clays. This was partly because they were cheaper than clays of equal quality of domestic origin, and partly because it was a good selling point, many of our clients being hypnotized by the popular bugaboo of the superiority of imported over domestic products. The imported raw materials we now employ are only a very small fraction of our entire consumption and are used only for a few special purposes. Domestic clays suitable for the manufacture of chemical stoneware are, however, not very widely distributed. Although our plants are situated in one of the greatest clay formations in this country, we can use comparatively little of the raw materials that are right at our door.

The expense of a long haul is, however, a great inducement to some other manufacturers to utilize local clays without due regard to their entire suitability. One of the difficulties thereby experienced is due to too short an interval between the temperature of vitrification and the softening point of the clay body. Thus the manufacturer using such clays who wishes to avoid deformation as much as possible, must be satisfied with incomplete vitrification, an attempt to improve the acid-proof qualities of his product by means of a heavily applied glaze. On the other hand, if he pays more attention to the proper vitrification of his product he cannot well avoid the distortion of the ware during firing.

#### HIGH DEGREE OF SKILL REQUIRED IN THE INDUSTRY

The present exhibition should do much to remove the prevalent idea that the manufacture of chemical stoneware as regards the necessary technical ability and skill is on a par with the manufacture of other clay products such as brick and tile. As a matter of fact the manufacture of this ware calls for a degree of specialized experience and painstaking skill exceeded by few other industries. This experience has in many cases been handed down from generation to generation; there are employed at the plants of our company a number of men whose forefathers worked at the first chemical stoneware plant in existence.

This is one important reason why it has been difficult to meet the demands of the chemical and explosives industry at the present time. This demand induced manufacturers of other ceramic products such as sewer pipe, brick and tile, fireclay, terra-cotta and hollow tile to enter the field. The efforts to adapt such plants which

are designed and equipped for the quantity production of a few simple shapes to a specialized industry such as this were foredoomed to failure, and this factor ultimately placed a still further strain on the few plants that possessed the necessary equipment, skilled labor and experience.

Moreover the entrance of such manufacturers into this field without the necessary experience and skilled help has undoubtedly done some harm to the industry as a whole, if such ware as they are able to turn out has been taken as a criterion of American chemical stoneware. There is little doubt, however, that the end of the war will also see the end of these peripatetic chemical stoneware manufacturers and that the industry will undoubtedly benefit from the demands that are being made upon it at the present time.

## Development of the Stoneware Industry

FIFTY-THREE years ago when the United States Stoneware Company was incorporated, the stoneware business was confined to the manufacture of crocks and jugs, and the maximum size it was thought possible to produce was a vessel of ten gallons capacity. Thirty years ago, however, this company conceived the idea that larger vessels could be made successfully and at once commenced experimenting. The result, through the aid of new methods, was a thirty-gallon crock. The demand for this vessel became so great for preserving meat, fruit, vegetables, butter, eggs etc. that its use became almost unlimited.

At this period the manufacturing of chemicals and explosives in the United States was in its infancy and the demand for acid-proof stoneware was correspondingly small. However, it was found necessary to increase the capacity of stoneware vessels to a still greater degree, the result being that to-day acid-proof stoneware is made to meet the requirements of customers in almost any desired form and size.

It may not be out of place to relate an incident that occurred back in the early 70's when Horace Greeley, the talented editor of the *New York Tribune* was the speaker at the exercises of laying the corner stone of Buchtel College in Akron, Ohio.

He ventured his conception of the process of making a stoneware jug: that a rope of suitable size was coiled in the form of a jug upon which clay was plastered, of desired thickness, and at the proper stage of dryness the rope was removed by drawing it out through the nozzle of the jug, being then ready for the kiln. A little later in the factory, however, he saw a jug maker standing on one foot and manipulating a pedal with the other, which caused a horizontal disk to revolve on which he was working a lump of clay with his hands through different stages until it became a finished jug ready for the kiln. He very amusingly admitted that the process of making a jug and his previous conception of it were much at variance. Thus verifying the fact that however wise one may be there is still more to be learned.

The process of making jugs and all other stoneware, to-day, is far in advance of that which was in vogue at the time above mentioned. Demand made it necessary to speed up, and processes employed now produce five

times as much stoneware in a given time. Perhaps no greater advance has been made than in the improvement of glazes.

Twenty years ago the U. S. Stoneware Co. became convinced that the cheap and ancient method of salt glazing which serves to cover up defects could be replaced with a glaze which would enter into and become a component part of the body of the clay. Thus began scientific experimenting which resulted in an exclusive glaze which displaces the antiquated salt glaze, the latter being the result of a few shovels of low-grade salt placed in the fire holes of the kiln which, at the point of burning off, fuses over the surface of the ware.

On the other hand the special glaze is applied to the ware in its partially dried state before firing and thus becomes a component part of the body of the ware. It is obvious that this system of integral, as well as a surface glaze, is far superior to a thin coating of salt glaze only.

We feel reluctant in mentioning the cruel war that the Kaiser has forced upon us and yet did we not condemn the atrocious military power of Germany which is striving to usurp the rights of the remainder of the world we should be lax in a duty which is incumbent on every patriot of the United States.

The impetus which the Kaiser's war has created in the many lines of business is recoiling upon him with tremendous force and will end in his defeat not only through force of arms but commercially as well. The slogan "made in Germany" has lost its effectiveness. Uncle Sam has awakened to the fact that he, too, can accomplish the difficult task of producing the numerous articles of commerce which formerly were an asset for Germany. The great resources of this republic protected as it must be by wise statesmanship will build up our industries and the United States will be known as the foremost nation of the world.

In meeting the requirements of the war the United States has certainly accomplished wonderful results. In every line the speeding-up process is going on to an extent that under other conditions would have been thought impossible. This connected effort to produce is perhaps no less pronounced in the line of chemical stoneware than in other important lines. The U. S. Stoneware Company has found it necessary to increase its capacity ten-fold that of normal times. When we have conquered the Kaiser, however, this condition may be changed to a certain extent, although the advances made in nearly every line of manufacturing which formerly went to Germany will be an asset for the United States.

## Direct Etchings On Glass

Diamond scratches are usually preferable to the usual wax and hydrofluoric acid etches because of being direct; however, by applying sodium fluoride in gum arabic paste to the glass surface, a platinum wire anode connected in electric circuit with the moist paste coating will liberate free hydrofluoric acid at the point of contact. With such an arrangement permanent and substantial marks can be directly placed on the glass. The cathode can be attached to a strip of cloth which the paste will cause to adhere to the glass.

## Home Made Optical Glass

The American Industry May be Epitomized by Saying that It Has Grown from Nothing in 1914 to an Export Business in 1918

By H. E. HOWE

SO SPECIALIZED has glass production become that window, plate, colored, heat-resisting, chemical, moulded, automatically-blown and optical glass each require their own organization for successful manufacture, and the trade merchandizing each ware is seldom fully familiar with other kinds of glass. The ultimate consumer, including the average chemist, has some difficulty in appreciating the differences.

Chemists are familiar, to be sure, with the research required to furnish glass having the peculiar characteristics of chemical glassware. But what of optical glass? In order that what has been accomplished in America in the past four years may be more fully appreciated, it will be useful to review something of the past one hundred years in optical glass.

Prior to 1870 there were but three notable exceptions to the general apathy in devising new types of optical glass. These were Fraunhofer, who had partial success but who failed to produce anything commercially and whose formulae were lost; an English committee headed by Micheal Faraday in 1825; and an English clergyman, Harcourt. Although the report submitted by Faraday in 1829 was of small practical value, it did have important directive influence. Harcourt was handicapped through lack of guidance to be had only from the spectrometer which was not available because his meltings were too small, but he recorded much of value and was one of the very first to experiment with new elements. We may say, therefore, that until Abbe's appeal in the late 70's, the impetus to improvement in optical glass may be credited largely to the Anglo-Saxons.

The efforts put forth by the glass makers concerned diminishing the color, increasing clearness and homogeneity in well-known crown glass and in obtaining greater refractive power and dispersion in flint than had been customary, but no one cared to experiment with new elements and compounds against which there was much prejudice. Crown glass was composed of potassium carbonate, with perhaps some sodium carbonate, lime and silicic acid. Flint contained no lime, substituting lead oxide therefor. Of course, many variations in amounts were used but there is no evidence that, excepting in an experimental way, any other elements than those named had been employed.

Abbe's appeal was from a scientific viewpoint, and without discussing the commercial aspect he emphasized the need of new materials with which to construct new microscopes etc. to be used in furthering scientific progress. Manufacturers were then, as today, reluctant to spend money on research without advanced guaranteed profit, and in this case there was no promise of large returns even if successful. It was fortunate, therefore, that Schott, the son of a glassmaker, was

attracted by the appeal and that the research work had the financial aid of the Prussian Bureau of Education and the Prussian Diet.

Until this work began, Germany was no better than second in optical glass production, France being the leader. But as in so many other instances, concentration with scientific method and ample finances was to lead to success.

### LIMITATIONS OF OPTICAL GLASS

It will be helpful here to mention some of the factors in the problem and then a little of what was undertaken under the name of the Jena Glass Laboratory. The glass flux must not act upon the material of the pot or crucible and in this manner absorb impurities. Elements which evaporate during the melt have a tendency to produce veins and so must not be used. These so-called veins or striæ or cords, as they are variously known, are of no consequence in many kinds of glass, but optical glass must be free from them and the slightest indication of them results in the glass being discarded. Large bubbles must be avoided, and all bubbles as far as possible, while for telescopes, microscopes, binoculars, eyeglass lenses and wherever the light is to be transmitted to the eye, no bubbles can be tolerated. Cloudiness, crystallization and any liability toward devitrification in the process of melting, cooling and subsequent re-heating must be avoided. The glass must be such that no stress will be produced when it is brought from the plastic to the solid state and it must not be hygroscopic or tarnishable in ordinary atmosphere. Optical glass must be as colorless as possible, although other characteristics are at times so desirable that color becomes a secondary consideration, as in special flints. Besides all these limitations, the product must have strength enough to bear the manipulation necessary in grinding, polishing, mounting etc.

Furthermore, refractive index, dispersion, absorption of light and density are values which should be maintained as constant as possible in successive melts of the same composition, for it is largely upon these values that the optician makes his choice and calculates his lens elements accordingly. For some optics it becomes necessary to refigure formulae for slight changes in these values between different melts and even to reconstruct grinding and polishing tools.

### EARLY EXPERIMENTAL WORK

When Schott and Abbe began their work, silicic acid was the only glass-making acid oxide in use. There was a tradition that boric, phosphoric and arsenic acid gave tarnishable glasses and, with the exception of Harcourt, no one had done much to determine the in-

fluence of the different metallic oxides upon the physical constants of optical glass. The first experiments were along this line and had to be empirical. They included the use of all the glass-making acid oxides with the oxides of boron, phosphorus, lithium, magnesium, zinc, cadmium, barium, strontium, aluminium, beryllium, iron, manganese, cerium, erbium, silver, mercury, thallium, bismuth, antimony, arsenic, molybdenum, niobium, tungsten, tin, titanium, uranium and fluorine.

The meltings were just large enough to yield pieces for spectrometric and refractive measurements and were made in porcelain, fine clay and platinum. The elements were introduced gradually in quantities of at least ten per cent and many were eliminated very early on account of rarity, volatility or coloring influence. It soon began to be demonstrated that the hitherto fixed relation between refraction and dispersion could be varied and that both ends of the spectrum could be lengthened.

The problem of new compositions was accompanied by that of providing suitable melting pots, technique in stirring and heating and in annealing to eliminate stresses. Special clays, "ripened" and carefully blended, make the final type of pot which required eight to ten months from the time it was laid down until ready for the furnace. After a great many trials and tests with polarized light, fine annealing was developed. It was determined that the temperature of solidification lay between 370 and 465 deg. C. and that by spreading the fall of 95 deg. over an interval of four or more weeks perfect results could be obtained. Accordingly, ovens were built with thermo-regulators and devices whereby they could be maintained at any point between 350 and 477 deg. C. and allowed to cool with any desired slowness.

#### NINETEEN GLASSES DEVELOPED UP TO 1886

Up to 1886 the net result of all this tedious work was nineteen glasses of essentially new optical properties. These may be roughly divided into four groups, flint containing boric acid, borosilicate crown, dense barium crown and phosphate glasses.

Flints containing boric acid are not so durable as the older types, but with them it is possible to make three lens objectives free from the secondary spectrum. The borosilicate crowns are important and find use in small objectives, prisms etc. They are of lower refractive index and dispersion than the ordinary crown glasses.

Dense barium crown glass contains barium and boric acid and is used in practically all anastigmat photographic lenses, but in order to obtain the necessary optical qualities it becomes necessary to approach very near to chemical instability, and this leads to difficulties in manufacture. The phosphate glasses proved unstable and subject to deterioration in use.

Since it would be an advantage if it were possible to compound a glass that would have certain calculated characteristics, efforts have been made to determine whether the characteristic of metallic oxides are persistent to the same degree in glass. Density, tenacity or tensile strength, resistance to crushing, elasticity, hardness, specific heat, conductivity of heat, cubical expansion, thermal endurance and chemical behavior have been carefully studied. In each instance the

properties have been determined from observations on properly selected glasses, and from the data thus obtained values have been assigned to the oxides. Other glasses have then been compounded with relation to these values and the results then compared with what had been expected from the calculations. Unfortunately, in practice the plan does not work out very well, although computed results differ in some cases from those observed by no more than 1½ per cent. The maximum difference, however, occasionally runs above 40 per cent.

#### RELATIVE INFLUENCE OF ELEMENTS ON GLASS

The elements having the greatest influence on the density of glass are barium and boron, while sodium and arsenic have the least influence. Calcium appears to have the greatest bearing on tenacity, and magnesium the least. Aluminium is responsible for the greatest hardness and calcium for the least. Auerbach fills the large gaps in the middle parts of the Mohs scale of hardness by inserting a crown glass between quartz and feldspar and two flints between apatite and fluor-spar. With these additions the scale in ascending order is gypsum, rock salt, calcspar, fluor-spar, two flint glasses, apatite, feldspar, crown glass, quartz, topaz and corundum.

Silicon has the greatest influence on resistance of glass to crushing, and potassium the least. Magnesium oxide appears to impart the greatest elasticity to glass, and zinc the least.

To determine the thermal endurance, polished cubes are heated to ascertain the greatest difference in temperature they can stand without cracking. Some glass can withstand a sudden rise in temperature far better than a sudden lowering of temperature, and the more the difference exceeds that temperature which can just be borne, the greater are the number of cracks produced. One glass, which in testing could withstand a difference in cooling of but 52.8 deg. C., was able to withstand a sudden elevation of 465 deg. C.

#### GLASS A SOLID SOLUTION

Glass is undoubtedly a solid solution in which silicic acid or other acid-forming oxide is the solvent. This accounts for much of the behavior of glass, such as the lack of homogeneity in optical glass. This improves as the glass ages, and since a readjustment of the molecules is rendered much more difficult in glass than in a liquid solution, a comparatively long time is required for the proper aging of optical glass. When this aging does not accomplish sufficient homogeneity, the optician produces an optically plane surface by means of local corrections obtained by hand polishing and frequent testing of the results thus secured.

The production of these new glasses to which others have since been added was taken up by Schott and Genossen with much success, stimulated by the demand for many new optical instruments made possible with the glass. It was thus that Germany soon became the world center not only for such glass but for all classes of optical instruments as well.

The French and English factories devoted their attention to specialties or, lacking an advertising bureau equal in efficiency to the German, made equal glass unknown except to old customers. It would be

worth knowing whether back in the 70's the Prussians had military optics in mind when their government helped to finance Abbe and Schott in their experiments!

#### MILITARY DEMAND FOR OPTICAL GLASS

When 1914 came, ordnance had been developed to a point such that whereas in our Spanish war 5000 yards had been considered a maximum range, we must now have range finders capable of reading accurately to 20,000 yards if they are to be efficient, and this necessitates high-grade optical glass in quantity to keep pace with the requirements of modern sized armies.

For some time, a few men had thought of producing optical glass in America. The glass companies could see no reason to finance the necessary expensive experiments unaided by the consumer, especially when the annual requirements were relatively small and no market was actually assured. Those using such glass were satisfied with their source of supply and consequently the little work that had been done was unsupported and half-hearted. Even after the war began, those vitally concerned retarded developmental work, strong in the belief that the war would be but a matter of weeks and the old source of supply soon again available.

Then came the demands of the Entente for range finders and binoculars beyond the capacity of their own or American optical works. Glass stocks melted away. The British Advisory Council recognized both chemical and optical glass manufacture as key industries and plunged into research and technical experiments. We began to realize that the best optics, even in our own military establishment, were made with Jena glass; that no more of that glass was forthcoming and that if business, our only consideration at that time, was to continue, we must make glass.

Fortunately, in the writer's opinion, there was in America a Belgian who had come here years before hoping to engage in the manufacture of optical glass. He was a technical man, and after making plate glass here in the absence of interest in American optical glass, he had returned to his ideal and was conducting some experiments in 1914. Engineers were called in, a larger plant provided and, inadequately assisted, this man began the commercial scale production of optical glass in America.

#### OBSTACLES TO BE OVERCOME

If error and failures were not to be expected, then the magnitude of the difficulties to be overcome has not been set forth with sufficient clearness. True, the work that had gone before was of immeasurable value and the new starting point well advanced, but formulae had never been published and were considered part of the stock in trade by European glass makers; a chemical analysis of such a complex silicate can do little more than furnish guidance in making up a melt. It seemed to require an unduly long time for the necessity of pure raw materials to become impressed upon the minds of those engaged in the work, whereas the very nature of the product requires careful control in this regard as had been made a point of importance by those propagandists interested in convincing America that optical glass was altogether too difficult a product to be attempted here. Sands thought to be of excep-

tional purity by the usual glass maker were found to contain sufficient iron to condemn them for optical glass where freedom from color is a requirement and no decolorizers such as manganese can be permitted. Lead oxide for flint glass must be of high purity and quite free from metallic lead, and so with item after item there are substances very likely to be present which can not be tolerated.

And pots! One of the large problems of the entire glass industry involving the study of clays which one well-known ceramic engineer says no one knows much about, least of all chemists. A large number of pots are required, for the usual practice is to allow the melt to cool in the pot which is thereby destroyed either during cooling or in breaking up and sorting the glass. Pots are of two types and are about 40 inches in diameter and height, though smaller ones are frequently used. The open pot is used for those melts not subject to the action of the products of combustion, while the closed or "monkey" pot affords almost complete protection, the only opening protruding at the side. Many pots have been made and used in less time than has ever been thought possible, and there have also been delays due to the breaking of these green pots in the melting arches.

Then there have been temperature problems, troubles with refractory brick and cement in the furnaces and all those factors which enter into the use of high temperatures under control. One of the tricks of the trade is the proper stirring of the melt. A water-cooled, fire clay stirrer is employed and this must travel in ever changing circles propelled by hand or power through a mechanical device. The European practice leans strongly toward hand-stirring because of the care required not to approach the pot walls too closely, thus bringing into the melt traces of the dissolved clay, and to vary the manipulation in accordance with changing conditions within the pot. Properly supervised mechanical stirring has given good results however.

#### REVIEW OF PROGRESS

What has been the progress under the stimulation of necessity in rapidly providing a key industry? The Bureau of Standards took up a portion of the burden, various glass makers began serious work, and through the solicitation of the members of the Naval Advisory Board, the Geophysical Laboratory of the Carnegie Institute applied its very considerable resources to the assistance of those already engaged in commercial scale experiments. America began to overcome her shortage of optical glass. There were and still are many problems. Some difficulty has been experienced in bringing glass makers of the old school to realize the exactness of the new requirements. "It is only a small bubble," but you can not have it in an eyepiece. "Just a single string," yet the presence of any striæ in a prism renders it unfit for range finder or binocular.

Prices have gone up and up, but not out of proportion to advances in cost of labor, fuel, raw materials and other items of production. For some grades of glass 20 per cent usable is considered a good yield, though this is materially increased in most instances. Output has been concentrated on glass used for military instruments and eye glasses and at the time this is

written America is in a position to satisfy her own requirements, to help her Allies and to export optical glass! One plant as early as February of this year produced more than sixty tons in one month; moreover, as many as six plants, great and small, are now at work, although some are not making much of a profit as yet, for the expense is heavy, the output small and the field restricted.

Other varieties of glass for microscope and photographic lenses will be added later, but meanwhile we are exploring new fields. One manufacturer has perfected methods for casting some optical glass very much as plate glass is poured on large casting tables and rolled out before annealing in a large sheet. This sheet or plate is then ground and polished, defects cut out and the remainder cut to size for final inspection. This has several advantages over breaking the glass to weighed portions and moulding these to size and shape or even sawing, notwithstanding the large loss in the grinding and polishing operation, amounting as it does to about 50 per cent of the melt.

The Bureau of Standards has undertaken research on glass pots with special reference to increasing the life of pots. Small-scale work with porcelain has yielded results which look promising.

From nothing in 1914 to ability to export in 1918 is a brief way of expressing what has been done. The key industry has learned to walk and we shall be able to make military optics to help us reach the Hun no matter how far he may run. This is the open season for German monopolies and they are being broken even as a good marksman shatters clay pigeons.

Cambridge, Mass.

### The Manufacture of Beakers

The question as to the thickness of the beakers and flasks has been the subject of careful consideration. Bohemian ware was always very thin, as the glass from which it was made was not resistant to heat. With resistance glasses it is possible to make beakers and flasks very much heavier than the Bohemian ware, and in this respect we, and the American manufacturers, have followed the practice of the makers of the Jena glassware. A 500-c.c. beaker should be about 0.8 mm. thick, and a 1000-c.c. beaker 1.0 to 1.2 mm. thick, but the articles must, of course, be evenly blown. Such articles as graduating flasks and X-ray bulbs must be blown exact to weight.

When a beaker is blown, it resembles a bottle, and the next stage in the process is to cut it to the proper height. The article is slightly scratched with a diamond, and placed on a revolving table, while a fine blowpipe jet plays upon it at the height of the scratch. If the goods are well annealed, and evenly blown, they crack off quickly and evenly, provided that the jet is properly adjusted. Badly annealed goods and badly blown goods crack off so as to leave jagged edges. Thus the efficiency of production depends very largely upon efficient first annealing.

The flanging and lipping of beakers, and the flanging of flasks, are operations which are carried out entirely by machines operated by girls. The designing of these machines did not call for a vast amount of ingenuity, but in perfecting the details it was necessary to study the processes very closely in the works.—*Jr. Soc. Chem. Ind.*

## Industrial Glassware

By S. R. SCHOLES

AMONG the lines of manufacture in America that have been greatly stimulated by conditions arising out of the great war is that of glass for industrial purposes. We imported most of this glassware before the war closed the European sources of supply. Perhaps the chief reason for that dependence upon Europe was the low tonnage estimated in making such ware. We were accustomed to producing tons of steel, while we imported cutlery. Similarly, we produced great quantities of plate and window glass, bottles, packers' goods, lighting glassware, tableware, even fine blown and cut glassware, because the demand was great and the tendency toward large-scale production, involving machines, could have full swing; but we imported scientific and industrial glassware, largely because we regarded the business as too small for consideration.

Another reason for hesitancy in entering competition with European workers lay in the fact that a large part of the scientific glassware came into this country duty-free, and therefore it was practically impossible for us to produce it, on account of the higher wages paid American workmen. Since the character of the glass itself which entered into scientific utensils and instruments was much the same as that required in the industries, this had a direct bearing on the production of industrial glass.

### STRONG DEMAND AT GOOD PRICES

An abrupt change took place when the war began in 1914. Not only were importations stopped, but also foreign competition. American manufacturers were both obliged to meet a new demand and allowed to obtain prices which warranted them in doing the necessary development work. Further incentive came from the expansion of chemical industry. New processes and enlarged plants required special pieces of glass apparatus and parts, and larger quantities of standard articles. The same effect was produced by the general expansion of the industries in 1915 and 1916. More steam boilers meant more gage glasses, more motors and machines, more oil-cups. When America entered the war, still further stimulation along special lines, especially optical glass, was manifest. The result has been that this country is rapidly approaching independence in the matter of glass for industrial purposes—if indeed that is not already attained.

However, the manufacturers did not at once grasp the situation to their full advantage. The wave of prosperity that began in 1915 brought a greater demand for glassware for household use, and factories whose equipment would have enabled them to produce large quantities of glassware for technical use declined at first to enter the field. They were busy enough as it was. In those days, few realized the length of war-time ahead, and peace seemed always only a matter of a few months. Therefore, it was argued, why waste money preparing for a business that could only be transient? But the demands of industry for glass became more insistent, and, with the curious reluctance toward the new and unfamiliar that has always seemed to characterize the makers of glass, they were supplied.

Discussion of the varieties and properties of indus-

trial glass in this article may well leave out optical glass, for that exceedingly important field has been well covered by the men who have so ably risen to the emergency and brought out with speed and thoroughness the vitally necessary glass, without which our best ships and guns would have been as futile as the blind. If ever in the future government appropriations for the bureaus engaged in purely scientific research should be grudging, their supporters need only point to 1917 and optical glass!

#### PHYSICAL REQUIREMENTS AND COMPOSITIONS OF GLASS

Glass for many, if not most, of its industrial uses requires exceptional strength, a low coefficient of expansion, and resistance to the attack of solvents of all sorts. It must be thoroughly annealed, for a residuum of internal strain that would be harmless in a window pane of a piece of table glassware, might be fatal in a gage-glass or a sight-feed tube. The articles themselves must be made to an accuracy of dimension approaching that of machine parts, a condition very unusual in ordinary glass articles.

The composition of glass to meet the requirements outlined is comparatively simple, although quite different from ordinary glass, such as would be found in bottles, for example. It is an old practice in this country to make a heat-resisting glass out of sand and borax. Such a glass is a sodium boro-silicate, and may be considered the foundation or type of heat-resisting glasses in general. The boric oxide serves a two-fold purpose: It replaces the alkali to some extent—the alkali is the constituent of glass having the greatest coefficient of expansion; boric oxide itself has the lowest. Another fortunate fact, is the reduced solubility or increased resistance to water and chemical reagents of the boro-silicates compared with the simple silicates.

The improvement of this sodium boro-silicate glass was the main problem to be solved. If pure fused silicate could be worked at a reasonable temperature, it would represent very nearly the ideal glass for industrial use. The more nearly its properties, except, of course, its softening temperature, are approached by any glass, so much the better for its durability. Therefore, the best heat-resisting glasses contain high percentages of silica, sometimes as high as 80 per cent. This makes them rather hard to melt and to work, but this very fact increases their utility for many purposes. In order further to decrease the solubility of these glasses—a very important matter in the case of gage-glasses, for example—it has been found advisable to add certain of the insoluble bases, such as alumina, zinc oxide, and magnesia.

The results reached in American factories are several closely similar heat-resisting glasses which are also very stable and resistant toward water and reagents of all sorts and toward high-pressure steam. So far as glass compositions go, American wares are now highly satisfactory. They are superior, in some lines, to the best that were ever imported.

Annealing is a matter that now receives more attention than formerly, for many failures of glass articles can be laid to the internal strain left by insufficient annealing. This, as everyone knows, must be removed by heating the ware to the initial softening point of the glass, then cooling it so slowly that both interior and surface portions of each piece reach the rigid condition

at virtually the same time. With the devices now obtainable, which make use of polarized light for detecting strain, glassware can be examined before it is sold, thus eliminating one source of loss and disappointment to both maker and user.

Accuracy of size and uniformity of thickness in glass articles require painstaking skill on the part of mold-makers and glassworkers. The developments here are also gratifying. When they have become convinced of this necessity, American workmen have taken a live interest in methods of manipulation to secure it, and have shown that there is little reason left to mourn the lack of imported ware for its workmanship.

#### TARIFF NECESSARY TO OFFSET OUR LABOR COSTS

There are no statistics available, but it is certain that the volume of business in glass for industrial uses is very large. It is also growing. The production of heat-resisting glass that will stand sudden and extreme changes in temperature has been followed by new applications for such glass. Many pieces coming under the general head of "sight-feeds" are being made, enabling the operators to see and thus control many processes hitherto "in the dark." Now and again a use is proposed which no glass can be expected to fill. On the other hand, glass parts could undoubtedly be introduced in many places in large scale chemical apparatus, where visibility is desirable but not now possible.

Summarizing the effect of the past four years on this phase of the glass industry, American manufacturers have proven themselves capable of supplying their country's needs, and have even gone farther and created new and better glasses than are made in Europe. A list of the varieties of glassware now made here that were not made to any extent in this country before the war, is given in the recent report of the Tariff Commission on "The Glass Industry as Affected by the War": Optical glass, laboratory or chemical ware, glass gage tubing, watch crystals, glazing glass, oven glass, glass brick, siphon bottles, photographic glass, and high grade picture glass and glass for spectacles.

This is an expansion worthy of note, and it has come in no sudden or spasmodic manner. It rests on a good foundation of careful study and work. The question of competition with Europe in industrial glass after the war will depend only upon price, for the quality of ware is assured. There must be, it is evident, a retention of suitable import duties to be paid by all alike. The unreasonable duty-free privilege, which discriminates against American manufacturers in favor of Europe and Asia, must be abolished. Then this healthy growth can be retained as a permanent branch of the glass industry in America.

#### Substituting Imported With Domestic Clays

In the past few years, many types of clay have been found in South Carolina and Georgia. Unfortunately, no suitable descriptive nomenclature other than Dry Branch, Gorden, Langley etc. has come into trade use. As the past geological experiences of a clay deposit controls the physical properties of the clay and no two deposits have been subjected to identical conditions, it follows that some judgment must be exercised in selecting a clay having properties similar to some particular foreign product.

## Recent Developments in the Manufacture of Chemical Porcelain

BY JOHN C. BAILAR

SOON after the outbreak of the present war, when German commerce was swept from the seas, any man who had a piece of chemical porcelain "Made in Germany" was inclined to keep it under lock and key. It would be decidedly inconvenient to run a laboratory without it and no one knew when or where more could be obtained when the supply on hand should be exhausted. But unknown to the scientific world the seeds of the chemical porcelain industry had already been planted in this country.

In the winter of 1910 a potter went to Golden, Colorado, seeking health. In order to pay expenses, he repaired an old pottery kiln that had long been in disuse and began the manufacture of cooking utensils on a small scale, he being the only workman in the plant. In 1911, the writer, struck with the excellent quality of the ware, suggested that he try some chemical porcelain. A few small crucibles were made using the same body and glaze that were used in the cooking ware. These were taken into the laboratory and given a thorough working test. As was to be expected, some of the test samples failed utterly, while a few compared favorably with the Royal Berlin porcelain that was in general use at the same time.

This showed the possibility of making good laboratory ware of the clay, and experiments were carried on in connection with the routine work until 1914, when the business was taken over by a company organized by Mr. Adolph Coors. The plant was enlarged as rapidly as possible, and early in 1915 was given over exclusively to the manufacture of chemical and scientific porcelain. That the venture has been a success is attested by the fact that the company now has twelve large kilns running at full capacity. This company maintains a large research department and the policy has been to perfect one article before beginning another. For example, in the beginning, only small crucibles, casseroles, and evaporating dishes were made and not until these were of the very best quality did the research department turn its attention to anything else. The high quality of the ware is due largely to this policy. The brain power of the entire force is focused on each article before it is given to the public.

### AEROPLANE SPARK-PLUGS

The research department, under the direction of W. J. Hazard, is now concentrating on a porcelain spark-plug for aeroplanes. The object sought is a spark-plug that will stand up under fifty hours' continuous use, besides being resistant to hard knocks and having several other properties desirable in spark-plugs. Present indications are that this plug will soon be on the market. The best porcelain aeroplane spark-plugs now in use are good for about thirty hours.

Coors chemical and scientific porcelain is now sold by practically every dealer in the United States, as well as in the principal cities in Canada, Mexico, South America and the war zone in France. The company manufactures all the wares used in the laboratory and plant, and stands ready to make any special apparatus ac-

cording to specifications. Special mention should here be made of the porous ware made by this firm. In comparative tests made in the United States mint, this ware lasted five times as long as the Royal Berlin. Some electrolytic processes have been completely revolutionized by the use of Coors porous vessels.

### LOCAL MATERIALS USED

The materials used by the Coors Company, except a small per cent of the glaze, are found within five miles of the factory. The clay is of the same formation as that from which the Golden fire-brick and assay crucibles are made. Concerning the latter ware a writer once made the following statement: "Mining engineers are in darkest Africa, in central China,, in the plateaus of the Andes and the steppes of Russia, but they have not yet got beyond the zone of the Colorado-made assay crucible." This is not a figure of speech but a plain statement of fact. In 1916, owing to the peculiarities in freight costs of transportation companies, both English and German assay crucibles were offered in the western United States for a less price than was asked for the home product, made from Golden clay; nevertheless they found no sale. But perhaps fire-clay goods should not be included in chemical porcelain.

### THE GUERNSEY CO. TAKES UP CHEMICAL-WARE

In contrast with the Coors pottery, the Guernsey Pottery of Cambridge, Ohio, was well established at the beginning of the war. They were making, among other things, high-grade cooking utensils. Realizing that there would soon be a demand for laboratory porcelain, this company lost no time in making such readjustments as were necessary. The change from cooking utensils to chemical porcelain was not great and by the time the last cargo from abroad was unloaded, they were in the market with porcelain that showed better tests than any "Made in Germany." During the past year there have been substantial advances in both quantity and quality of Guernsey ware. They now advertise "more than three hundred different items," which number ought to give variety enough to satisfy the demands of the most exacting chemist. The products of the Guernsey and the Coors companies have been tested and approved by the U. S. Bureau of Standards.

If the need should arise, either the Guernsey or the Coors pottery could supply the needs of the United States, leaving nothing to be desired in either quality or quantity.

In addition to these two firms, other companies are turning their attention to laboratory ware and neither the analyst nor the manufacturer need have any fear of the future. It can safely be predicted that if any German laboratory ware should ever find its way into this country, it will be given the same reception that was given to German fire-clay goods in 1906.

Research Department,  
Great Western Sugar Co.,  
Denver, Colorado.

**Scratches on the Ground.**—Clay has been an important writing material throughout all the ages. The sheet of paper on which this is printed is essentially kaolin in a more convenient form than the bricks of the library of Ninevah.

## Chemical Stoneware\*

### Preparation and Selection of Materials, Acid-Resisting Tests, and Annealing Ware

By A. MALINOVSKY

THE manufacture of chemical stoneware is a separate and distinct branch of the ceramic industry. It is a branch that has received but scant attention in this country as most of this class of ware was imported. Now that importations have been cut off, it is essential that we produce chemical stoneware equal if not superior to the imported article. This must be done if the chemical industry is to continue its growth and supply us with the many chemicals that have heretofore been imported or made in limited quantity only.

Chemical stoneware is made in a great number of shapes and sizes, ranging from the simple evaporating dish to the most intricate arrangement of pipes and vessels and to containers of great size. It requires a skillful workman for building up these various shapes and the utmost care in handling and burning them; but more than anything else, it requires the close and careful attention of a competent ceramic chemist to make selection of raw materials, supervise mixture and manufacture, from grinding to firing and to vary the processes to produce ware that will fulfill the requirements of the particular use to which it is to be put. A good chemical stoneware should resist the action of hot and cold acids of all kinds (excepting hydrofluoric acid), be able to stand sudden changes in temperature, and be impervious to moisture.

#### THE SELECTION AND MIXING OF CLAYS

It is the usual practice to mix different clays to produce a body similar in character to porcelain; therefore, mostly those stoneware clays are used which contain enough flux to produce, at a high heat, a body with a very close structure. If stoneware clays are not at hand, a low grade of fire clay can be substituted. The fire clay is burned at about 1400 to 1500 degrees centigrade, at which temperature the iron and other impurities will act as the flux; or the fire clay can be mixed with an impure clay which has a very low fusing point. In this case the fire clay serves as the skeleton to preserve the shape of the articles from deformation, whereas the impure clay serves as the flux which at a high heat binds the particles of the fire clay into an impervious body. Other cheap fluxes can be added such as lime, or furnace slag, since the color is of no great importance. In this latter case, there is a chance for the acid to attack the iron and subsequently the clay body, thus disintegrating the whole body to a sponge-like mass.

Great care should be taken to produce a uniform body, since this is very essential in the manufacture of chemical stoneware. The best result is obtained by mixing and blunging the mixture, or only the fusible part, which will be the fusible clay (preferably all the mix should be blunged), and by then screening in order to remove all coarse particles. The surplus water is then removed with the filter press.

It is very necessary to screen the clay and remove all the coarse particles, particularly when taping and faucets

are required which must be made to fit tight. The spigot and faucet are usually made from the same material as the body, some manufacturers preferring to grind the material finer for the spigot and faucet than for the body. The joints in spigots or faucets have to be ground with water and sand or emery to make a close fit. If the coarse material is not removed, tight fitting of spigot or faucet will be impossible.

The body mix should be high in silica and yet plastic enough to permit the shaping of large pipes and vessels, such as still condensers, acid containers and other vessels used in the chemical industry. At the same time it should possess an interval of from 200 to 300 degrees centigrade between complete vitrification and deformation.

#### NEW MATERIALS SUCCESSFUL

It is in this interesting field of ceramics, more particularly refractories and chemical stoneware, that the writer has been doing research work during the past several years of strife. The company with which I am connected has undertaken the development and perfection of processes by which certain waste materials and minerals, heretofore unutilized, can be employed in making various ceramic products.

It is gratifying to be able to say that our efforts have been successful. Many tests of the ware, both in the laboratory and under actual working conditions have given results comparable with the best imported products. Materials from many different states have been used in this connection and their suitability under the process proven.

The composition of the stoneware is highly vitrified and the ware has a structure similar to that of igneous rocks, excepting that it is more nearly homogeneous. It can be made of as close and fine grained a structure as porcelain. This stoneware consists of unfused and fused particles, held together by a vitreous bond. The different mineral particles are enveloped by the fused particles, giving a strong interlocking structure which resists the action of moisture and of acids.

#### SOME SOLUBILITY TESTS

A test made by the author in our own laboratory yielded some interesting results. Two crucibles and one vase were placed in a gas fired dry oven and were gradually heated for 72 hours to 110 degrees centigrade. After they were allowed to cool in the oven to 90 degrees centigrade they were placed in a large jar until cooled to room temperature and then were carefully weighed. The small crucible weighed 192 grams; the large one 934 grams, and the vase 621 grams. The crucibles and vase were immersed in water for 48 hours, then removed, and, after drying the surface with blotting paper, carefully weighed again. The results obtained indicated that the large crucible had 0.856 per cent absorption, the small one 0.521 per cent, and the vase 0.0325 per cent. The same crucible and vase were again dried and weighed as before. The large crucible was found to weigh 933.542 grams, the small one 192.000 grams, and the vase 620.372 grams.

They were then filled with commercial concentrated sulphuric acid, 66Bé., and the two crucibles placed on a 14-inch iron pan filled with sand. Two inches of sand separated the test pieces from the pan. Heat was ap-

\*Read at the June meeting of the American Institute of Chemical Engineers, Gorham, N. H.

plied and boiling continued for a period of 12 weeks. The temperature of the sand and acid was taken day and night. The record shows an average temperature of 128 deg. C. Since we had no gas regulator at hand the temperature varied from 136 to 120 deg. C.

The vase was subjected to the same test, excepting that the flame was applied directly to the vase and was therefore more difficult to maintain at a constant temperature. Especially was this true during the night when the gas pressure was stronger than during the day. Forty-two pounds of acid were used, since the test pieces had to be filled whenever the acid fell below half the capacity.

After the twelve weeks boiling, the fire was turned out and the test pieces were allowed to cool. They were then washed some thirty times with brush and water, placed in a drying oven, heated to 140 deg. C., cooled and washed again, and placed in the drying oven and heated to 140 deg. C. They were then placed in a jar containing fused calcium chloride. After 24 hours they were removed and weighed with the following results:

|                      | Grams Weight | Per Cent Loss |
|----------------------|--------------|---------------|
| Large crucible ..... | 932.854      | 0.0737        |
| Small crucible ..... | 192.000      | .....         |
| Vase .....           | 619.863      | 0.0981        |

One of the crucibles was then broken and reduced to a fine powder which was passed through a 16 mesh sieve and then through a 20 mesh sieve. One hundred of the largest grains remaining on the 20 mesh sieves were selected and thoroughly washed with distilled water, then dried to 110 deg. C., cooled in a desiccator, and weighed. The 100 selected grains weighed 180 grams.

They were transferred to a platinum crucible and treated with the acid mixture of 10 parts of concentrated nitric acid, plus 25 parts of concentrated sulphuric acid, plus 65 parts of water. The platinum crucible with the contents of the 100 grains and acids was placed on wire gauze on which a  $\frac{1}{8}$ -inch piece of asbestos  $1\frac{1}{2}$  inches in diameter was placed, and gently heated to boiling and held at that temperature until the water and nitric acid were vaporized and all sulphur fumes driven off. The whole operation took four hours. The crucible was then allowed to cool.

Water and nitric acid were again added and reheated to boiling and held for 10 minutes. The contents of the crucible were transferred to filter paper and washed thoroughly until the wash showed no acid reaction with blue litmus paper. It required about 1500 cc. of water to wash the grains free from acid. The grains were then dried in a drying oven to 110 deg. C. for five hours, then transferred to a desiccator and weighed. The weight of the grains was 179 grams, showing a loss of 0.56 per cent.

The grains were then transferred into the platinum crucible, which was previously heated and weighed, heated for 20 minutes and blasted for 10 minutes, then cooled in the desiccator. The loss shown was the same as before.

#### MICROGRAPHICAL EXAMINATION

Microscopic examinations were made of several samples by Professor Rolin B. Salisbury, geologist, University of Chicago, in order to determine the structure of the material and the composition of this stoneware after

it is burned. The writer has also made microscopic examinations of many samples.

The examinations have shown that in all cases, in the vitrified composition, the burning has produced fusion enough among the materials used in making the ware to develop a glass as in lavas. It could be noticed on the slides that this glass served as a binding material for the original grains which were not fused. These grains were bound together by the glass in very much the same way as are the crystals of some igneous rocks by the glassy uncrystallized parts of lava.

In physical composition, therefore, this stoneware is like a compact igneous rock which is but partly crystallized. The texture of the body is such as to indicate the possibilities of a high polish, so that spigots and stoppers could be ground to perfect joints; and the grain is so fine and even that clean-cut lettering and carving is possible. This has already been proven very satisfactorily.

In describing the material, Professor Salisbury notes that "under the microscope the material is seen to consist of grains of quartz, orthoclase, magnetite, and altered ferromagnesia mineral in a glassy ground mass. This ground mass was developed in the burning and is the result of the fusion of parts of the substance of which the body is composed.

"The pore space is about eleven per cent, but it should be noted that this is not the amount of space that will take up water, since the pores are in the glass and not accessible to water. The grains of quartz are angular (many) or rounded (fewer), apparently as they were before burning. They show little, if any sign of corrosion. The corners of the angular grains remain sharp, but there appears to be a very thin film of clear glass surrounding each.

"The feldspar grains, both orthoclase and plagioclase, are much altered on the outside, and grade into the ground mass without sharp demarkation. The smaller grains are altered throughout. Under the microscope the original grains are seen to be broken up into extremely fine fragments which are bound together by isotropic material. The effect of the heat appears first to have fractured the grains and then to have fused the material along the cracks. The little particles into which the feldspar is broken average about 0.002 mm. in diameter. There appears to be considerable kaolin, probably such as occurred in the original material from which the body was made.

"The ferromagnesia mineral is so much altered that its original character is not recognizable. But little of it is present. It is now altered to magnetite, surrounded by a brownish stain. It grades into the ground mass. The ground mass is of glass, filled with minute (.002 mm.) particles of quartz and feldspar. The union of the original particles seems to be as complete as in extrusive igneous rock which contains some glass."

It is interesting to consider the action which takes place between the alkaline earth and metals and oxides of silica, aluminium, and iron during the burning period.

When the fire is started, the hot air passes through the kiln warming up the green particles; and when the temperature of 110 deg. C. is reached inside the kiln, the hygroscopic moisture is forced to leave the green ware, and at a higher temperature the chemically combined moisture is driven off and oxidation follows. When this

is completed the bases and the silica and alumina combine in order to form various silicates. Naturally the base which has the lowest fusing point will fuse first, reacting with the finest grains of silica to form silicates, and then, in order, follow the next ones which have a higher melting point, until all the required eutectic mixture is in a sufficiently glutinous state to bind all the non-fused particles with a glassy bond to a dense body.

At first the feldspar substance in the body begins to soften; the fused feldspar is then attacking the clay substance while it is melting. However, the melting point of feldspar must not be misunderstood. Feldspar does not melt to a liquid and flow, but only softens and adheres to the more refractory particles. It is well known that the greater the proportion of undissolved material present in the mixture, the longer the ware will resist deformation. This fact is proven by the hard translucent porcelain, where the potter builds up his frame work with kaolin to insure the articles against becoming deformed within the heat limit.

#### COOLING AND ANNEALING

When the ware is sound and is vitrified to imperviousness, firing has ceased, and cooling and annealing commences. Annealing is a process of gradually cooling, which allows the silicates to settle and rearrange themselves in a condition of equilibrium. The annealing process is just as important in producing chemical ware as all of the processes in the manufacture of ceramics, to avoid molecular strain; yet it is the least understood by most manufacturers.

The importance of the annealing process is frequently to be seen in the case of glass tiles on sidewalks which have broken or disintegrated into powder. The reason lies in the fact that the glass, in the molten state, was poured into the steel mould and pressed. In this way the glass was chilled rapidly and the molecules on the surface rushed to adjust themselves. As a result, the glass becomes intensely solidified which prevents the molecules of the interior from rearranging and uniting. We can easily see that the glass is in a state of continual strain and is prevented from collapsing only by the intense rigidity of the exterior walls. As soon as the surface of the glass is scratched or broken, the whole tile breaks into pieces, sometimes making a violent noise. This is true with the stoneware also. If cooling is hurried too much, the ware will be brittle and invisible cracks will occur.

Cooling too slowly will cause too much of crystallization of the magna; therefore the cooling can proceed very fast until the temperature has fallen to red heat—say 1000 or 800 deg. C.—when freezing temperature of the eutectic has been reached; from then on cooling has to proceed very slowly, especially when the body is high in silica.

A very good idea of the formations and behavior of the silicates in the glass or ceramic bodies can be illustrated as follows:

Let us imagine a dancing hall, everything quiet; all persons present are comparatively motionless. Some may be in a standing position eagerly waiting for action, others seated. The orchestra commences to play. Every one hurriedly looks for his or her partner and then the couples dance around the hall in greatest order, one pair after the other. We never find that all the persons

commence to take action at once, but pair after pair until all are dancing, excepting the people on whom the catalytic action of the music has not taken effect.

As soon as the orchestra stops playing, the couples return to their places quietly and rearrange themselves orderly for the next action. Had there been any disturbance in the orchestra or among the dancing couples, the music naturally would have stopped at once and every pair would have parted in disorder, running unsettled in all directions. From this we learn that the orchestra had assumed the function of a catalyzer to produce action in the persons present in the dancing hall.

This is also true with the heat. When burning chemical stoneware, the heat is in reality not consumed; it only performs the action of forming the different silicates in order to produce vitrification in the ceramic bodies to make it impervious to moisture and acid. Thus we see that the function of the heat as a catalyzer is exactly the same as the music; every molecule of the heat is given up as soon as it has accomplished the required result.

## Portland Cement Construction for Chemical Works

By MAXIMILIAN TOCH

PORTLAND cement and the cements from which it has been derived have always shown a tendency to porosity and the necessity for either an added material or a coating in order to make it impervious has always been apparent. The Romans recognized the necessity for water-proofing Pozzuolan, the composition of which is quite similar to that of our Portland cement. Two thousand years ago they recommended the use of a small quantity of grease in order to water-proof their structures. Our rush to finish construction of all kinds demands the use not only of a water-proofing material but one which shall lubricate at the same time and overcome the shortcomings of the man at the mixer. For this purpose, there are two distinct types of water-proofing, both of which are patented, one practically composed of stearate of lime, free from glycerine, and the other composed of a glyceride of a fatty acid mixed with a colloid.

There are such vast quantities of nitre cake that are dumped into rivers and creeks near chemical works that the free sulphuric acid in the nitre cake has a tendency to dissolve out the Portland cement foundations of adjacent structures, and for this purpose, newer water-proofings for Portland cement have been invented which make the concrete relatively acid-proof, and after the forms have been removed, it has been found necessary to apply acid-proof coatings to such Portland cement foundations to prevent the disintegration from the acids that pollute the streams.

The scarcity of steel and the high price of lumber construction has done much for the progress in the building of Portland cement tanks for chemical works, the only feature being that special coatings have had to be devised, the kind depending upon the chemicals used. The thinner oils and many of the heavier oils cannot be stored in concrete unless the concrete is particularly dense and well finished, and even then it is not worth while taking a chance, but the application of an oil-

proof coating prevents concrete from being disintegrated. Even acids may now be stored in concrete tanks provided the tanks are finished with acid-proof brick linings which have been set in a heavy bituminous binding material.

The great advantage of a Portland cement tank for chemical works is that, assuming that it is built correctly, it will last forever, and that of course cannot be said of a wood or steel tank.

There are some chemical works that use large quantities of nitre cake. I know of one concern that built an entire storage shed of acid-proof concrete for storing nitre cake, and it has proved that concrete can be made impervious to acid, a feat which was regarded as impossible before the war.

### The Journal of the American Ceramic Society

A journal that is a pioneer in its field is always the subject of most careful scrutiny. When that field is representative of one of the oldest phases of human endeavor the cause for attention to the new publication is multiplied many fold. There has now appeared the first issue of the *Journal of the American Ceramic Society*, a monthly journal devoted to science and technique of the ceramic industries.

The American Ceramic Society belongs to the older family of scientific societies in the United States. The first meeting of the society, which was in reality a little family gathering of a small group of ceramic enthusiasts, was held in Columbus, Ohio, in February, 1899, and from that meeting grew the present organization due largely to the guiding genius of Prof. Edward Orton, Jr., of Ohio State University. The society is, therefore, in its twentieth year of vigorous and active life. The membership has increased from that early day until at present there are over a thousand enrolled.

In the American Ceramic Society, the term ceramic is synonymous with "silicate industries" and the interests and activities of the society include all branches of the clayware, glass and cement industries as well as enameled wares of all kinds and in addition other closely allied products are included, chief among which are abrasives, gypsum and lime. Few people realize the gigantic proportions of these ceramic industries. The products of the three major divisions alone (clayware, glass and cement) aggregate over \$400,000,000 per annum.

In the earlier days the society consisted of one main organization only. With increased activities and with enlargement in its scope of usefulness it became necessary to organize Local Sections for the following localities: St. Louis, Chicago, Central Ohio, Northern Ohio, West Virginia, Beaver, New England, New York State, New Jersey, and Pacific Coast.

Student Branches exist in Ohio State University, New York State, University of Illinois, Iowa State College.

The publication work of the society has, up to the present time, been confined to the issuing of its annual volume of *Transactions*. Twenty years ago this was a small, feeble effort, very creditable for the then existing state of our knowledge of the science of the silicate industries. This annual volume has shown continuous growth and the 1917 volume comprises 707 pages of

well-edited contributions. The American Ceramic Society's *Transactions* have been known for many years throughout the world as the standard reference books on the silicate industries.

This remarkable growth in strength and influence of the society has made it essential that periodical publication of the researches and other activities of the society members be undertaken and the monthly *Journal of the American Ceramic Society* is the logical result.

The first number is a very attractively prepared journal of seventy-two pages. It is well edited and well printed on good paper. The contents of the first number are as follows:

#### Editorials:

To the Public.

The Fuel Curtailment Orders.

The National Research Council.

Edward Orton, Jr.

#### Original Papers and Discussions:

Kaolin in Quebec—Keele.

Special Pots for the Melting of Optical Glass—Bleininger.

The Effect of Gravitation Upon the Drying of Ceramic Ware—Washburn.

Test of a Producer Gas-Fired Periodic Kiln—Harrop.

Notes on the Hydration of Anhydrite and Dead-Burned Gypsum—Gill.

Meetings of the Local Sections, American Ceramic Society.

The present officers of the society are: President, Homer F. Staley; vice-president, A. F. Greaves-Walker; treasurer, R. K. Hursh, and secretary, Charles F. Binns. Trustees: A. F. Hottinger, E. T. Montgomery, R. D. Landrum.

Membership in the society is open to anyone interested in any branch of the ceramic industries and application should be made to the society. All members receive the *Journal* gratis; to non-members the subscription price is \$6.00 per year (12 issues), payable to the secretary in advance.

### Graphite Supplies For 1918

About 30,000 tons of graphite suitable for crucible manufacture will be needed in 1918. If freight and market conditions and an improved labor situation favor the shipment of domestic graphite about 8000 tons of flake of crucible grade, exclusive of dust, can be marketed in this country in 1918, an increase of more than 100 per cent over the production in 1917. If the freight conditions that prevailed in the autumn of 1917 should recur the domestic production of No. 1 and No. 2 flake will hardly exceed 2500 tons. If the domestic production could be stimulated to its maximum capacity, reasonable assurance of a steady market given, and encouragement offered to new plants a production as high as 12,000 tons might be reached. The situation is more favorable with respect to noncrucible graphite. The requirements for 1918 will be between 28,000 and 31,000 tons, which may probably be supplied by domestic, artificial, and Mexican production. Amorphous graphite was produced in 1917 by five mines in Colorado, Michigan, Nevada, and Rhode Island. The production was 8301 tons, valued at \$73,481, compared with 2622 tons, valued at \$20,723, in 1916.

## Carborundum Refractories

### A Comparative Account of Silicon Carbide Refractories With Those in General Use—Great Improvement Made in Thermal Conductivity, Efficiency and Strength

By S. C. LINBARGER, B. S., CER. E.

EVER since its inception, one of the vital problems of the ceramic industry has been the question of suitable refractory materials, both for use in its own factories and as a product which will meet the demands of the other industries which require the highest grade of refractories. These materials must have sufficient strength under normal conditions to carry the weight of the structure of which they are an integral part and must, furthermore, have sufficient refractoriness to carry this same load under the extreme heat conditions to which they are subjected.

It has always been customary to regard heat insulation in a refractory material equally desirable with resistance to fusion, probably because these properties are intimately associated in the case of the common type of fire brick or sagger mix of the aluminous silicate type which are highly refractory and are such poor conductors of heat that in comparison with metallic substances they can safely be classed as heat insulators. However, only a superficial study of the problems involved in the burning of ware in saggars or muffle kilns reveals the fact that heat conductivity of the refractories used, besides being highly desirable, is a potent factor in the economical operation of the process.

For many years men connected with all branches of the clay working industry have been seeking a more effective means of burning clay products in a shorter time and with less fuel. Especially is this true and the need for it was never greater than at the present time when the vital needs of the country must be met with a maximum of fuel economy. Most of the efforts have been along the line of improving kiln design so that the maximum amount of heat is extracted from the gases of combustion before they pass into the stack. In most cases this is accomplished by passing the gases from the hot zone or chamber over ware in other zones which is at a much lower temperature and thereby gradually raise the temperature of the ware by the utilization of the sensible heat of the gases after they leave the combustion zone. All agree that when ware is being burned at a high maturing temperature one of the vital points of fuel economy is to get as much as is possible of the heat of the gases transferred from them to the ware.

In the pottery and allied industries where the ware is burned in saggars or by setting on shelves or bats a solution of this problem resolves itself into the proper selection and utilization of a refractory material which will more quickly and more easily absorb the heat from the surrounding gases and transmit and deliver it to the center of the bearing structure. The essential physical properties which govern the selection of the best refractory for this purpose are strength, specific heat,

thermal conductivity and emissivity. Of course in connection with these it must have the required refractoriness and be able to withstand the necessary handling without breakage.

The element of strength, both transverse and compressive, is one of the properties which is too often overlooked in the selection of the proper refractory material. By using a material of high mechanical strength, both under normal and heat conditions, not only is the loss by breakage materially reduced, but primarily the walls of the building material can be very much thinner, with the consequence that the heat is conducted to the ware much more readily, to say nothing of the saving in kiln space and the smaller amount of heat required to bring the building material up to the maturing temperature of the kiln.

The specific heat of the refractory is the important physical property required in calculating the number of thermal units that are really wasted in bringing the large mass of the supporting material from normal temperature up to the finishing temperature of the kiln. In some instances where the weight of the bats and saggars is equal to or more than the weight of the ware which it protects and supports, it means a considerable item in the burning costs.

As a concrete example of the exact factors involved in the transfer of heat from the hot kiln gases to the ware, let us consider the specific case of a plant which is burning ware in saggars, the saggars being set in stacks so arranged in the kiln that their entire peripheral surface is exposed to the kiln gases. The spaces between the sagger stacks can be assumed to be chimneys and the velocity of the gases through them will depend upon their size and shape and also upon the draft of the kiln. Assume the hypothesis:

1. That the turbulence is such as to make a fairly uniform temperature in the kiln at any point on one of a system of surfaces which is symmetrical about the gas passage; and

2. That the average temperature on these surfaces is the average of the temperature of the gases at ingress and egress.

It is evident that these hypotheses mean that the turbulence is controlled by some finite law that a graph indicating the temperature gradient through the kiln would be a straight line. These hypotheses hold fairly well if the motion of the gases is so slow as to make the turbulence negligible or if the motion of the hot gases is so great as to make the turbulence very great. The quantity of heat then that will pass through the walls of the supporting refractory medium in a given time and be delivered to the center of the saggars will depend upon the excess temperature of the gases over the

ware and the thermal conductivity of the refractory and will be a direct function of the emissivity of it.

When heat waves strike a body some of them are absorbed and some of them reflected unless the body be what is known as a "black body," in which case all of the heat rays are absorbed. All other bodies absorb a definite percentage of the heat waves which strike their surfaces and reflect the rest. The exact ratio of conduction and radiation being dependent upon the surface and the character of the body. This ratio for any material is what is known as the emissivity factor of that material. Under like conditions the same ratios hold true for the radiation of heat units from any solid body into a gaseous medium. The emissivity factor for any substance can then be determined experimentally by finding the radiation per second per unit surface area per degree difference in temperature. As the quantity of heat that will cross the boundary plane between the solid and the gas per unit time is dependent upon a factor other than the thermal conductivity of the solid, it is readily observed that the emissivity factor of the refractory which is usually neglected is an important consideration in the absorption of the greatest amount of the sensible heat from the gases which come in contact with it.

Crystallized silicon carbide or "carborundum" as it is most commonly called has long been recognized as having unique physical properties which make it peculiarly adaptable in the construction of highly refractory materials. However, up to the present time it has not had a very wide application in this field owing to its high price and also to the lack of sufficient quantities to supply other than the abrasive industry, which of course is its field of primary importance.

At the present time there are two types of crystallized carborundum refractories which have been highly developed. The first type which goes under the trade names of "Refrax" and "Silfrax," depending upon whether the crystallization of the aggregate is large or small, is made according to patents which in general cover the silification of mixtures of carbon and silicon carbide or carbon forms and their subsequent conversion into carborundum by subjecting the carbon to silicon containing vapors at the heat of the electric furnace. The carbon is converted into carbide of silicon forming a dense interstitial binder or matrix between the crystals. Of course there are many modifications of this process but the essential characteristic of this type of refractory is that the final products obtained are pure silicon carbide.

The other type which is known as "Carbofrax" is the type most generally applicable for use in the ceramic industries. It is made by bonding graded crystallized carbide of silicon grains with various percentages of a mixture of special refractory clays or other bonding substances.

When bonded with even a high percentage of clay binder, brick which contains carborundum gives very great refractory values. However, since the refractoriness of a conglomerate refractory mass is a direct function of the amount and character of the least refractory constituent, it is recognized that the ideal condition to be obtained is that the amount of binding material used be the least consistent with the requisite

strength; and that the vitrification temperature of the binder be as high as is commercially practical. Mixtures of grits and methods of bonding are employed which insure a very dense body of low porosity with but a minute percentage of refractory clay binder and at the same time allow the manufacture of large and intricate shapes.

Experimentation has shown that crystalline silicon carbide forms at 1840 deg. C. and dissociates at 2240 deg. C. into its elements, the silicon being volatilized and the carbon remaining as graphite. No softening or fusing occurs below the dissociation temperature which is shown by the sharp and perfect forms of graphite pseudomorphs or skeletons which are left when silicon carbide dissociates. This is in direct contrast to most other refractories such as silica, chrome, and fireclay brick which soften at a temperature several hundred degrees lower than their fusion point.

Fig. 1 shows the emissivity curves of several common refractories. The curves for this factor were accurately

FIG. 1.—HEAT EMISSIVITY CURVES

plotted from results obtained by very complex experimental methods which are too cumbersome to describe in this paper. It will be noted that the emissivity of both classes of crystallized carborundum brick is much higher than either magnesite or chrome brick and almost double that of clay brick at a temperature of 200 deg. C. and higher.

| Material        | Specific Heat | Thermal Conductivity | Compressive Strength, Lb. per Sq. In. |
|-----------------|---------------|----------------------|---------------------------------------|
| Fire brick..... | 0.192         | 0.0034               | 1,050                                 |
| Sagger mix..... | 0.187         | 0.0033               | 1,340                                 |
| Magnesite.....  | 0.220         | 0.0071               | 4,800                                 |
| Chrome.....     | 0.174         | 0.0067               | 3,900                                 |
| Refrax.....     | 0.162         | 0.0275               | 12,500                                |
| Carbofrax.....  | 0.180         | 0.0243               | 14,700                                |
| Silica.....     | 0.191         | 0.0020               | 2,300                                 |

Table I shows the results of some tests made on the most common types of refractory materials. The specimens tested were selected at random as being representative of the average product of that particular class of refractory. No attempt was made to compare different brands of the same material.

A comparison of the thermal conductivities of the materials reveals the fact that the carbofrax brick will conduct about three times as much heat as magnesite, seven times as much as the sagger mix and twelve times as much as a silica brick in the same period of time.

Fig. 2 graphically represents the relative efficiencies of various refractory materials as obtained by using the values of specific heat, thermal conductivity and emissivity in the formula for the law governing the transmission of heat from a gas to the interior of a solid body. The figure is arbitrarily based with the abscissae representing relative efficiencies while the ordinates give difference of temperature. A study of the results demonstrates that the materials with a high emissivity factor and high coefficient of heat conductivity show several times the efficiency of those with correspondingly lower values with the same thickness of wall. Compressive tests of the materials show that the carborundum refractories have a load-carrying capacity over ten times as great as the sagger mixture under normal temperatures. Under heat conditions this ratio is considerably increased because there is absolutely no softening of this class of material at 1350 deg. C. while the sagger mix at the same temperature shows a deforma-

FIG. 2

RELATIVE EFFICIENCIES OF REFRACTORY MATERIALS

tion with a load of 50 pounds per square inch. In fact, blocks of bonded SiC are used as bearing blocks in making load tests on refractories at high temperatures. It would then be possible to use refractories for supporting ware in kilns with walls one-tenth as thick as is ordinarily used with the aluminous silicate type of refractories. Since the amount of heat transmitted by a solid is inversely proportional to its thickness, the efficiency already demonstrated by high thermal conductivity and emissivity would be multiplied by ten.

Aside from the importance of fuel economy, high thermal conductivity and heat capacity of crystallized carborundum impart to refractories made from it the property of withstanding the most sudden temperature changes because any variance in the temperature of the surface is quickly communicated to the whole mass and the heat is rapidly dissipated. Thus, the molecular work resulting from it is uniform and refractory shapes of this type can be subjected to the most sudden variations of temperature without being cracked or disintegrated.

As silicon carbide is not subject to any molecular changes being formed at 1850 deg. C. in a crystalline state and has an extremely low coefficient of expansion, no porous structure is necessary and a high density can

therefore be obtained. This is not possible with most refractories since they contain ingredients which have one or more allotropic forms and must be made open and porous to successfully withstand the internal stresses. The low coefficient of expansion and high density of carborundum brick permit the construction of solid structures in places where the leakage of heat and gases through cracks in the walls due to alternate contraction and expansion is a detriment to the successful operation of the process.

In an effort to obtain the complete combustion of a fuel there is a growing tendency to increase the temperature of the fireboxes or furnaces. Ordinary firebrick, even of the best grade, fuses under the high temperatures developed and is attacked by the fluid ashes of the coal. This fluid ash which so violently attacks fireclay brick forms a brownish coating or glaze over the exposed portion of the carborundum brick which is unattacked by any additional fluid ash which is formed in the firebox. Owing to their extreme hardness this type of brick does not suffer from deterioration as the common refractories do when struck by the tools of the fireman during the process of cleaning the fires.

Carborundum is manufactured by passing an electric current through a mixture of sawdust, sand and coke in a long rectangular resistance furnace. By the utilization of an enormous amount of electric energy, the central portion of the furnace is brought up to about 2200 deg. C. at which temperature the silica is volatilized. One molecule of silicon combines with one of carbon forming a core of pure crystallized SiC or silicon carbide between the electrodes in opposite ends of the furnace. Immediately surrounding this is a zone of the amorphous variety of carborundum which is commercially known as firesand. Chemically it is a mixture of several silico-carbides which vary in composition from  $\text{Si}_2\text{C}_2\text{O}$  to  $\text{Si}_3\text{C}_3\text{O}$ . This represents a partial reduction of silica by carbon or a solid solution of silicon carbide in silica.

This material is also highly refractory but owing to its lower heat of formation and lack of definite crystalline structure it is not as stable under extremely high temperature as the crystalline variety. However, it has a wide application in places where a higher degree of refractoriness is required than can be obtained in the best grade of fireclay brick.

Finely ground firesand when mixed with a bonding material such as kaolin or high grade plastic fireclay, makes a refractory which can be moulded in place or plastered over the surface of a lower grade refractory to protect it from the cutting action of impinging flames. Owing to the fact that even the intense reducing heat of an oil flame does not cause any modification of the firesand, it has come to be a recognized material for the linings of brass furnaces of all types. It is also used as a protective coating for the brick work of furnaces, bag and baffle walls and the walls of potter's kilns. For this work it is mixed with water and sodium silicate, and oftentimes a small amount of clay to increase the adhesion, and applied to the walls in a slip condition. Refractory materials made of mixtures containing silicon carbide are now being used in various capacities in the ceramic as well as the metallurgical industries.

## From A to Z With the Exhibitors

**THE BALTIMORE COOPERAGE CO.**—A complete line of miniature tanks which are exact reproductions of the larger sizes made for the chemical, drug and acid trade.

**GENERAL FIRE EXTINGUISHER COMPANY**—Grinnell sprinkler head in actual operation in a glass house or cabinet. At intervals a fire will be started on the floor of this cabinet which automatically opens the sprinkler head and releases the water, putting the fire out. Sprinkler supervisory service will also be illustrated. In charge of exhibit: FRANK V. SACKETT, HOWARD E. BRANCH.

**GEORGIA CHAMBER OF COMMERCE**—Through the courtesy of T. Poole Maynard, this organization will have a representative at his booth to give information regarding Georgia mineral products.

**GORDON ENGINEERING CORPORATION**—Two standard Gordon dryers, type B- and F-2. Since our entry into the war this company has developed a type of dryer for primers, detonators, explosives, etc., in use in Government arsenals. In charge of exhibit: HAROLD B. HARVEY.

**GLENS FALLS MACHINE WORKS.** Demonstration of a rotary sulphur burner; the Wood's machine, used as a save-all or washer for gun cotton as well as wood pulp; and a consistency regulator for regulating consistency of any kind of pulp. In charge of exhibit: JAMES H. HAINES, FRED CHAFFEE and M. G. TIBBETTS.

**EMIL GREINAR COMPANY.** A display of chemical glassware manufactured in the company's own plant in New York City, including accurate graduated glassware, burettes, pipettes, flasks, cylinders, thermometers, hydrometers and apparatus for gas analysis. In charge of exhibit: FREDERICK KRAISSE, PAUL TODTSCHINDER.

**GROCH CENTRIFUGAL FLOTATION, LTD.** A working model illustrating this system of flotation as applied to the treatment of valuable mineral-bearing ores. This system and appliances have been developed since the war. In charge of exhibit: FRANK GROCH, L. W. LEDYARD, W. E. SIMPSON.

**GUERNSEY EARTHENWARE COMPANY**—A complete line of chemical laboratory porcelain consisting of crucibles, casseroles, evaporating dishes, dry pots, concentric rings, desiccator plates, funnels, combusted boats, mortars and pestles, porous plates, retorts, etc. In charge of exhibits: ALLEN L. GOULDING.

**HANOVIA CHEMICAL AND MANUFACTURING COMPANY**—Apparatus for heat measurement and control; thermoelectric pyrometers, new model indicators and recorders, thermocouples, protecting tubes, central control and signal-system units, standardization equipment. Electric resistance thermometers, indicators, testing sets, thermometer bulbs. Electric furnaces and Impervite porcelain. The new developments of this company since we entered the war are new model pyrometer indicators and recorders and Impervite porcelain. In charge of exhibit: R. W. NEWCOMB.

**HARDIDGE CONICAL MILL COMPANY**—Working model of a Hardinge mill together with a large size glass model to show the interior workings. There will also be on exhibit a sample of Hardinge WE lining which

permits lining a mill without exposing any of the bolt heads to the action of the balls. In charge of exhibit: E. W. LAWLER.

**HAUSER-STANDER TANK COMPANY**—A standard rectangular tank with sides and bottom cut out to show the method of rodding and bracing. A special type of crystallizing tank will also be shown with a few staves removed to show the interior arrangement. In charge of exhibit: S. HAUSER, JR.

**HAYNES STELLITE COMPANY**—Standard bar stock and bits, lathe tools of the arc-welded type, followed and inserted two milling cutters, end mill and some miscellaneous lathe tools. There will also be exhibited some products of the instrument and cutlery department, including surgical and dental implements, table knives, forks, spoons, ladles, pocket knives, mirrors, saws, etc. The new developments of this company since the war began consist of surgical instruments furnished the War Department. In charge of exhibit: ROE L. JOHNSON, H. S. DUNHAM, T. C. EDWARDS.

**HELLENIC CHEMICAL & COLOR COMPANY, INC.**—A line of dyestuffs, dry colors and some chemicals. This company has developed several colors since the war began, which were formerly imported from Germany. In charge of exhibit: MESSRS. WILLIAMS AND HAWTOW.

**FRANK HEMINGWAY, INC.**—Dyestuffs, mill supply specialties, intermediates and chemicals. This exhibit will feature a new stripping compound and a perfect substitute for cream of tartar for all but edible purposes. In charge of exhibit: T. F. O'KEEFE, H. H. FOSTER, H. ARNERUSTER.

**S. S. HEPWORTH COMPANY**—Belt-driven and electric centrifugal machine in operation. The electric type is particularly adapted to chemical plants requiring a machine of large capacity but not running continuously. This machine has been developed for special service since the entry of our country into the war. In charge of exhibit: BRUNO C. LECHLER, CHARLES A. ALCOTT, FOSTER E. BABBITT.

**HERCULES ENGINEERING CORPORATION**—Illustrations of a general line of chemical apparatus and the Hercules chlorine compressor. In charge of exhibit: R. D. KEHOE.

**THE HERCULES POWDER CO.** Samples of chemical products such as pyroxylin solutions, water-proof belt cement, lacquers, aeroplane dopes, together with samples of kelp from which solvents and potash are extracted; samples of potash fertilizer. On Wednesday morning motion pictures and slides of the harvesting of kelp and views of the plant where it is refined will be shown. The products resulting from the treatment of kelp have all been developed since the beginning of the war. In charge of exhibit: G. C. O'BRIEN, A. B. DEAN, J. H. RILE, J. P. BUTLER and C. A. HIGGINS.

**HEROLD CHINA AND POTTERY COMPANY.** Demonstration of porcelain ware, American made, showing how it will withstand heat and sudden changes of temperature.

**HOLLY PNEUMATIC SYSTEMS, INC.**—Pneumatic conveying installation with a suction dust filter, demonstrating the possibility of conveying pneumatically and economically all material from units not over 1½ in. in diameter down to material as fine as dust. Experiments are under way on a large scale for the recovery of pot

ash from cement kiln gases. In charge of exhibit: L. F. HOLLY.

HOOKE ELECTROCHEMICAL COMPANY—Chlorine products. In charge of exhibit: Representatives from New York office and Niagara Falls plant.

HOSKINS MANUFACTURING COMPANY—Electric laboratory furnaces and hotplates; laboratory triangles, gauze and tongs; electric tool furnaces; recording and indicating pyrometers, thermocouples and thermocouple protecting tubes. In charge of exhibit: CHARLES S. KINNISON.

HOWES PUBLISHING COMPANY—An exhibit devoted to the American Dyestuff Reporter. In charge of exhibit: A. P. HOWES.

HUFF ELECTROSTATIC SEPARATOR COMPANY—An electrostatic separating machine or the treatment of ores of graphite, zinc, tungsten, manganese, copper, molybdenum. During the exposition the machine will be in operation on the treatment of various materials which may be submitted for preparation or concentration. In charge of exhibit: H. B. JOHNSON.

HUNTER DRY KILN COMPANY—Compounds of different kinds of rubber dried and processed by the Hunter system. Photographs of various installations. In charge of exhibit: HARRY HUNTER, OREN M. RAGSDALE, ARTHUR B. STONEX.

F. C. HUYCK & SONS. This company has specialized in woolen cloths for mechanical purposes, particularly the paper making trade, and in conjunction with the development of the chemical and dye industry in this country during the war have turned their knowledge of wool and machinery to the supply of woolen filter cloths which they will exhibit, showing the various stages in the production, and the materials from which they are made. In charge of exhibit: H. M. ASHBY, F. J. MCGOVERN.

IMPERIAL COLOR WORKS, INC.—An exhibit in conjunction with IMPERIAL DYEWOOD COMPANY and JOHN H. HEALD & COMPANY, INC. Dry and pulp colors and dyewood extracts; dry colors for the paint, printing ink, leather, textile and kindred trades; pulp colors for surface coating and paper mills; special dyes for wool dyeing and producing army khaki. In charge of exhibit: MESSRS. JACK AND CONSTANTINE.

IMPERIAL DYEWOOD COMPANY, INC. A display of dyestuffs in paste and crystal form showing the crude tropical woods from which the dyestuffs are made. In charge of exhibit: ROBERT CONSTANTINE.

INDEPENDENT CHEMICAL COMPANY. A display of heavy chemicals and acids which they manufacture for several companies. In charge of exhibit: O. CRISPENE, T. SULLIVAN.

INDUSTRIAL FILTRATION CORPORATION. Vacuum filters. In charge of exhibit: WM. H. HARDER, JR., W. H. LOUGHREY, HENRY B. FABER, H. W. CONRAD, J. R. HESS. INNIS, SPEIDEN & Co. Display of chemicals and allied products.

JACQUES WOLF & COMPANY—Chemical specialties for the textile industry and dyestuffs. The following products have been developed subsequent to the war: Hydro-sulphites, sulphur blacks, chrome black, gallant. In charge of exhibit: DR. ALFRED PFISTER, S. F. CARTER, C. E. HESSLING, WALTER DEUBLE, C. G. BOOTH.

JANNEY, STEINMETZ & COMPANY—Cold-drawn steel shapes suitable for the chemical industry, and hot-drawn high pressure cylinders for various gases and liquids under pressure. In charge of exhibit: N. W. SCHLATER.

JEWELL POLAR COMPANY—Steam, gas and electrically operated stills. A steam still in operation in connection with the Crane Company's adjoining exhibit. In charge of exhibits: A. C. JEWELL.

KALBFLEISCH CORPORATION—Mineral acids, metallic salts, paper makers' chemicals, alum, lacquers and thinners. The special features of the exhibit are permanganate of soda, sulphate of soda, anhydrous for standardizing dyes and colors. Among the products not made by this company prior to the war are permanganate of soda, alum, satin white and boro phosphate crystals. In charge of exhibit: V. P. DAVIS.

KALBPERRY CORPORATION, ENGINEERS—The investigation and determination of chemical investments. The design and operation of chemical plants. A recent development is a method of all-masonry construction for concentrating, Glover, Gay Lussac and denitrating towers and similar chemical construction in which leakage due to cracking has been obviated. In charge of exhibit: P. W. WEBSTER.

KEWAUNEE MANUFACTURING COMPANY—Chemical laboratory desks of various types; apparatus cabinets, fume hood, special plumbing fixtures and accessories for chemical laboratories. In charge of exhibit: O. T. LOUIS, CHARLES RESS, R. A. HANNA.

KEYSTONE MINERALS COMPANY—Rotten stone, Keystone black filler, velvet filler, mineral black. The new features of the exhibit are a fine grade of rotten stone and a new mineral black. In charge of exhibit: J. T. AND F. J. O'BRIEN.

KING CHEMICAL COMPANY—Sulphuric and nitric acids and sulphur dioxide. The latter was originally imported by this company from Belgium but it has since developed a plant for the manufacture of this chemical. In charge of exhibit: O. CRESPELERS.

MAURICE A. KNIGHT—General line of acid proof chemical stoneware apparatus. In charge of exhibit: MAURICE A. KNIGHT, CHARLES N. DENNISON.

H. KOPPERS COMPANY—Illustration of the essential features of the Koppers by-product coke ovens. Samples of coke and other fire products. The particular development of this country since the war began is the construction of a number of toluol recovery plants. In charge of exhibit: H. C. KIRKPATRICK.

LEEDS & NORTHRUP COMPANY—Electrical apparatus and equipment for the heat-treatment of steel, including the automatic signalling system used in connection with recording temperatures. Apparatus developed since the war began includes a portable a.c. galvanometer and an apparatus for the rapid electrolytic determination of carbon in steel. In charge of exhibit: E. A. KEELER, E. B. ESTABROOK.

ARTHUR D. LITTLE, INC.: Examples of the application of chemical engineering and chemistry to industries. In charge of exhibit: H. E. HOWE.

WALTER E. LUMMUS CO.: Continuous concentrating still, periodic column still, dissolving apparatus, "metro-lift," tower scrubber. Present activities practically

limited to war requirements, providing apparatus for solvent recovery, stills for benzol, toluol and naphtha, acetone and alcohol apparatus, evaporators and stills for products for poisonous gases. In charge of exhibit: C. F. TEARS, G. S. HOUGHLAND, J. T. STONE, E. W. BARTRAM.

EMIL E. LUNGWITZ: Kelly filter press, hand-operated and fitted with the latest automatic locks. A special Kelly filter press made of solid copper will be exhibited to show that these presses can be made of different metals for specific purposes. In charge of exhibit: C. L. BRYDEN, H. L. DICK, PAUL BARTELT.

LUZERNE RUBBER CO.: Hard-rubber specialties and standard goods. Items of interest to the chemical trade are hard-rubber piping, fittings, buckets, etc., for the handling of chemicals, acids and alkali solutions. In charge of exhibit: C. D. WILSON, HARRY E. CASE.

MACBETH-EVANS GLASS CO.: Chemical glassware, including beakers, flasks of various shapes and sizes, Petri dishes and covers, watch glasses, crystallizing dishes, funnels and moist chambers. In charge of exhibit: H. P. FULLER, J. W. HARVEY.

MARDEN, ORTH & HASTINGS CORPORATION: A full line of the dyestuffs and intermediates manufactured at the various plants of the company, samples of heavy chemicals and special brands of animal, vegetable, oriental and fish oils. Considerable attention attaches to this exhibit on account of the fact that many of the products were first developed in America by this concern.

MATHIESON ALKALI WORKS: Exhibiting jointly with Arnold, Hoffman & Company, Inc. Bleaching powder, liquid chlorine, caustic soda, soda ash, bicarbonate of soda and modified sodas.

T. POOLE MAYNARD: Geological, industrial and chemical engineering. Representing the Georgia Potash & Chemical Company, the Georgia Mineral Products Company, the Interstate Clay Company, the Southern Ball Clay Company. The Georgia Chamber of Commerce is at Mr. Maynard's booth, by courtesy. In charge of booth: T. POOLE MAYNARD, V. R. WAITE.

FREDERICK MAYWALD. Consulting chemist.

MENDLESON CORPORATION: Chlorinated lime, caustic soda and lye. There will also be on exhibition some of the small amber glass tubes each containing one gram of chlorinated lime, which are supplied to soldiers in the trenches for sterilizing drinking water. Each tube will sterilize a barrelful or field waterbagful of water and make it safe to drink. In charge of exhibit: J. M. STEMLER, P. E. ERIKSON, J. E. SAMMOND.

MERCK & Co.: Medicinal chemicals and chemical reagents for use by physicians and in chemical laboratories. The company's works at Rahway, N. J., have been considerably extended since the war began in 1914 and have produced for the first time a number of new products such as carbolic acid, salicylates, hydroquinone, aniline, nitrobenzine, acetanilid, acetphenetidin, resorcin, paranitraline, phenolsulphonates, betanaphthol compounds, paraphenylenediamine.

METALS DISINTEGRATING COMPANY. Exhibiting samples of zinc dust, aluminum dust, tin dust and aluminium paint. Since the United States entered the war this company has developed on a large scale a process for the production of aluminium powder suitable for military purposes. In charge of exhibit: S. G. SCHATZBERG, W. H. NAUGLE.

B. MIFFLIN HOOD BRICK CO. Chemical stoneware of a hundred different sizes and shapes specially manufactured and adapted to acid-proof masonry construction. This material is suitable for the construction of towers, scrubbing towers, oxidation and denitration, also concentrators, Glover and Gay Lussac towers and tanks; spiral rings for tower packing. In charge of exhibit: B. MIFFLIN HOOD, J. J. NEER, G. BERGEN FORD.

MINE & SMELTER SUPPLY COMPANY. Massco clay goods and refractories made from Colorado clays; McCool pulverizer used for pulverizing assayed samples, chemicals, coal, etc.; Samson laboratory crusher; Lindsay low-pressure oil burner. One of the features of the exhibit will be a small Wilfley concentrating table, used for concentrating ores and for recovering and separating such industrial wastes as brass, copper and alloys. In charge of exhibit: J. SHEDDEN, E. S. TOMPKINS.

MINER-EDGAR COMPANY. Chemical products from the plant of the Seaboard Chemical Company and the Alcohol Products Company, manufacturers of wood alcohol and acetate solvents for special industries. Washed and floated clays for ceramic and paper uses. The chemical part of this company's business has been largely developed since 1914. In charge of exhibit: R. H. FRENCH.

MONARCH MANUFACTURING WORKS, INC. Stoneware sulphuric acid and chamber sprays in operation. The entire exhibit includes sprays in general, lead stop valves, lead check valves, lead syphons, furnace oil burners. The stoneware spray for nitric acid has been produced since this country entered the war. In charge of exhibit: T. W. MURPHY.

MONONGAHELA VALLEY TRACTION COMPANY. An exhibit of all products manufactured or mined in the company's territory; full information on bituminous coal, the most important resource; samples of glass-sand and coal pyrites. The West Virginia Geological Survey will contribute its library of state publications. The cities of Fairmount, Clarksburg, Parkersburg and Marietta will each contribute samples of their manufacturing industries. Important developments since the beginning of the war are the manufacture of gas and ammonium sulphate by the Lynn process, and the manufacture of sulphuric acid from coal pyrites. In charge of exhibit: For WEST VIRGINIA GEOLOGICAL SURVEY, PROFESSOR KRAK; For MONONGAHELA VALLEY TRACTION COMPANY, FRNACIS MCQUILLIN.

MULTI METAL COMPANY INC. Screens for bolting, sifting and filtration, made of brass, copper, bronze, phosphor-bronze, Monel metal, perforated metals. Pulmosan safety devices for the protection of workmen exposed to polluted air or poisonous fumes; helmets, breathing masks and respirators. In charge of exhibit: FREDERICK STERN.

NASH ENGINEERING COMPANY. Hydroturbine air compressors and vacuum pumps; Jennings turbine vacuum and low-pressure boiler feed pumps. The display will include pumps in actual operation. Special machinery devised to meet contingencies brought on by the war includes a successful chlorine compressor which, however, will not be exhibited. In charge of exhibit: IRVING C. JENNINGS, HOWARD M. WYLIE, G. B. WRIGHT.

NASSAU VALVE & PUMP COMPANY, INC. Acid-resisting valves, fittings, centrifugal pumps and castings for

hot or cold corrosive liquids, especially sulphuric acid and sulphates. In charge of exhibit: RAYMOND K. SNAVELY.

**NATIONAL ANILINE & CHEMICAL COMPANY, INC.** Exhibit of dyeings of American and German colors, both having previously been subjected to the same tests of scouring, pulling and exposure to light and weather. About 130 National dyes; a full range of intermediates; a quantity of dyed material and dyed garments of all descriptions: special dyeings of alizarine and indigo; a dyeing unit of a colorist's laboratory in which dyeings will be made on request. While the greater part of the dye exhibit represents developments since the war, special attention is called to alizarine and indigo. In charge of exhibit: L. J. MATOS.

**NEW JERSEY ZINC COMPANY.** An exhibit of products including various brands of zinc oxide, lithopone, ochre, zinc dust, zinc chlorine, (both liquid and fused), sulphuric and muriatic acids, as well as the newly developed U. S. P. zinc oxide now being produced in commercial quantities for the first time in the history of the country. Zinc cadmium and barium salts will be on exhibition, as well as samples of the finish which can be secured by the use of zinc pigments in paints. Among the metal products of the company are spelter, spiegel-eisen, gold and silver bullion. The application of zinc dust in sherardizing and protective coating work will be illustrated. The production of U. S. P. zinc oxide for making pharmaceutical preparations is a new development, the output of the company at the present time being figured in ton per day. In charge of exhibit: W. H. HENDRICKS.

**NIAGARA ELECTRO CHEMICAL COMPANY.** Cyanides exhibited in the booth of the ROESSLER & HASSLACHER CHEMICAL COMPANY.

**NICHOLS COPPER COMPANY.** Copper sulphate crystals; refined copper wire bar; pyramids illustrating the metallurgy of copper, containing ores, concentrates, blister, refined copper, silver and gold; pyramids of packages of Triangle brand blue vitriol; samples of gold, silver, selenium, copper oxide and nickel sulphate. In charge of exhibit: W. C. BENNETT and G. P. HITCHCOCK.

**NITROGEN PRODUCTS COMPANY.** Exhibiting jointly with ARNOLD, HOFFMAN COMPANY, INC. Sodium cyanide, lump and powdered, red and yellow prussiate of soda and anhydrous ammonia.

**NORTON COMPANY.** Comprehensive display of alundum and crystalline refractories and laboratory wear. Demonstrations will be made on a laboratory scale of physical and chemical properties of these materials. Apparatus of various kinds will be in operation. In charge of exhibit: HAROLD R. SAVAGE.

**OHIO POTTERY COMPANY.** Chemical porcelain ware, including beakers, casseroles, crucibles, evaporating dishes, filter plates, funnels, mortars, spatulas, etc. In charge of exhibit: GEORGE E. and C. D. FRAUNFELTER.

**OLIVER CONTINUOUS FILTER CO.** A small filter with accessories operating on cement dust from a potash recovery plant to show how every step on a continuous and automatic filter takes place; other types and accessories are also shown. Many types of filter have been manufactured since we entered the war for handling products not made in United States before the war. In

charge of exhibit: E. L. OLIVER, R. G. WALKER, L. GAZARIAN.

**ONTARIO BUREAU OF MINES.** Ores and minerals from the Province of Ontario, together with chemical and metallurgical products of the same. Of special interest will be the exhibit of nickel and molybdenum ore, together with their metallurgical products. A wide range of metallic and non-metallic minerals will display the extent of the resources of Ontario. In charge of exhibit: W. K. MCNEILL, W. R. ROGERS, THOMAS W. GIBSON.

**ORGANIC SALT & ACID COMPANY.** Chemical products comprising salicylic acid, salol, sodium salicylate, acetyl-salicylic acid, acetanilid, tri-phenyl phosphate.

**PAGE STEEL & WIRE COMPANY.** Samples of wire fabric for factory enclosures and fences. One sample will be made of American ingot wire and another of "Copperweld" wire. Copper-clad wire for electrical transmission has been widely used during the last year in the construction of cantonments. In charge of exhibit: W. T. KYLE.

**PALO COMPANY.** Laboratory supplies, including Durieux filter paper, Hess-Ives tint photometer, Despatch electric ovens, Link automatic water stills, Rhotanium. In charge of exhibit: M. J. SEAVY.

**THE PRAUDLER CO.** A display of acid-resisting, glass-lined steel tanks. A feature of this exhibit is a tank that has been used for boiling inorganic acid for one year and is still in good condition. In charge of exhibit: W. E. FOSTER.

**PHILADELPHIA QUARTZ COMPANY.** An exhibit showing the different forms of silicate of soda. In charge of exhibit: JAMES G. VAIL.

**PHILADELPHIA TEXTILE MACHINERY COMPANY.** Model of Proctor dryer for the drying of paints, chemicals, etc.; also samples of various paint colors and other materials being dried in the Proctor dryer. In charge of exhibit: W. R. MURRAY.

**PNEUMERCATOR COMPANY.** Various types of pneumatic equipment to demonstrate the method of measuring the weight, volume or depth of liquids contained in tanks. In charge of exhibit: WILLIAM THOMAS.

**POWDERED COAL ENGINEERING & EQUIPMENT COMPANY.** In actual operation, a small unit for burning powdered coal. The equipment is applicable to the firing of low-pressure and high-pressure heating boilers of the kind commonly used in apartment houses and small office buildings. It also lends itself to application in metallurgical work, forging, heat treating, etc. In charge of exhibit: H. B. PRUDEN.

**PRECISION INSTRUMENT COMPANY.** Apparatus for regulating and measuring the efficiency of combustion: CO<sub>2</sub> recorder; draft gages; flue gas analyzers. The particular feature of the exhibit will be an air speed indicator for aeroplanes which has been developed and produced since we entered the war. In charge of exhibit: ABRAM T. BALDWIN, C. E. CONWAY, and Messrs. VINCENT and GILSON.

**PRODUCT SALES COMPANY.** Industrial minerals such as acid tower quartz, feldspar, ground silica, barytes, crude and ground soapstone. A special feature of the exhibit will be chemically pure asbestos for laboratory use. In charge of exhibit: HENRY N. HANNA, Miss N. M. VOLOSHEV.

### Germany in The Melting Pot

THE weak spot in Germany's armor at the beginning of the war was in her shortage of the non-ferrous metals. To ameliorate this a national inventory of all the metals was made from which a sort of military registration was evolved of candle sticks, church bells, chandeliers, copper roofs, brass pipes, bronze statues, token coins, etc., with the varying classifications as to their military essentiality. All Belgian articles were given class 1-A immediately. The Hohenzollern and Hapsburg bronze statues were placed at the other end of the line in class 5-G. All others were given intermediate classifications.

All went well during the early days of the draft. The calling out of class 1-A was a jubilant assemblage. Early successes brought in many tons of scrap. The work of reclaiming on the battle-fields became an important factor in the supplies of copper, tin, nickel, etc. However, in spite of all this, the disbursements were so enormous that the draft gradually passed on into the deferred classes. The great classic statues of Schiller and Goethe lost their dignity and their value as scrap-metal soared so high that the labors of the sculptors were petty items on the German account books.

With the cremation of the Schillers and Goethes in the foundry cupolas, for work in the front lines, the wonder soon grew as to why the Friedrichs der Grosses and Wilhelms did not leave their park pedestals, for surely poets were not of greater need at the front than the Deutschland-über-Alles commanders of yore. Indignation among the enlightened population of Germany grew to such an extent that three bronze Hohenzollerns enlisted at Berlin, three more at Cologne, two from Munich and one each from several towns along the Rhine, to save their fame.

Another interesting feature in the German metal situation is the exalted uses of iron. The military honor crosses of the rusty metal have no more intrinsic material value that the lucky horseshoe of legendary fame. Not satisfied in limiting the iron "toting" to the soldiers, Germany has instituted iron coinage. The fractional mark coins are no longer of copper and nickel but are forgings of Siemens-Martin steel, the nobility of the non-corroding ferro-silicons being too high for the office. Thus the embossed German eagle has been elected to join the Schillers, Goethes, Wilhelms and Friedrichs of the metal world in their new vocations.

The really satisfactory thing about this is the clear evidence afforded of the lack of metals on the other side of the Rhine. The fate of the monuments and coins typifies Germany—all are in the melting pot.

## Our Preeminence in Metal Production

IN VIEW of the important part played by metals in the prosecution of the war, it is a significant fact that neither Germany nor Austria holds first rank in the production of a single vital metal. The Allies, on the other hand, not only have the advantage of the United States' leadership in base-metal production, but they also control the output of the precious metals. Taking the latter first, we find that Great Britain controls over 60 per cent of the output of gold, through the mines of South Africa and Australia. The United States leads in silver production. Russia is the most important source of platinum, so necessary for making heavy acids for explosives; and while that unfortunate country may not be a comforting asset just now, there is abundant opportunity to capitalize her metal resources if we proceed in the right way.

Among the base metals, the United States takes first place in the production of lead, copper and zinc, all useful in the manufacture of small ammunition. In iron and steel, also, we have normally led the other nations, producing about 40 per cent of the world's total. This has been of incalculable value in the making of ships, guns and projectiles, and in the tremendous amount of construction that has been under way. Aluminium for light alloys used in aeroplane construction is of vital importance, and here again the United States is the fortunate leader in production. With nickel available in large quantities from the mines of Canada and refineries of our own country, and tungsten from Colorado and California, we have the basis for alloy steels of the first importance. Indeed it would be difficult to find a brighter galaxy, and it is safe to say that no other nation is so favored. The advantage which it represents cannot be adequately estimated because so many factors enter into our ultimate success; but if a careful analysis could be made and reliable values assigned to our various advantages we venture the belief that our preëminence in metal production would stand near the head of the list.

## War Minerals Bill Ready for Signature

WE WERE advised yesterday that the War Minerals bill, which has been pending for so many months, had finally passed both houses of Congress and awaited the President's signature. It is exceedingly unfortunate that there has been so much delay in passing this needed legislation, for there is no doubt that a great deal of work has been postponed until the attitude of the Government could be determined. There were features in the House bill, however, which became the subject of so much controversy that it soon became apparent that delay was inevitable. The price-fixing and licensing features were the subject of attack, as was also the amount of the revolving fund which had to be provided for operations under the terms of the bill. When the House bill went to the Senate, that body struck out everything following the enacting clause, which is an effective parliamentary procedure in amending a bill, and then added ten sections of its own drafting. The price-fixing feature went by the board; the amount of the revolving fund was changed from \$10,000,000 back to the original \$50,-

000,000; provision was made for a system of contracts between producers and the Government; and in general a better bill was drawn up than was conceived by the House. The Senate was more conservative, and yet the hope is expressed that its bill will be quite as effective as the House intended its own should be.

In brief, the bill authorizes the President to enter into contracts for the production or purchase of certain ores, minerals and metallurgical products, and to use, allocate or sell them in the interest of the national security and defense and the successful prosecution of the war. In order that producers shall feel properly safeguarded and warranted in producing materials for sale under the terms of the bill, it is provided that contracts for purchase may cover a period of two years after the end of the war, but not longer. The President is further authorized to requisition and take over the materials under consideration, as well as mines and metallurgical works capable of producing them, and to operate such mines or works in any manner he may deem best. Just compensation is to be made to the parties from whom the mines or works are taken, and provision is made for determining what that just compensation may be, in case agreement cannot be reached without resort to litigation. We fancy that prospect of having to litigate to determine a settlement will not make a strong appeal to those whose mines or works may be taken over.

The sum of \$50,000,000 is appropriated as a revolving fund with which to carry out the objects of the bill. Corporations may be formed by the President to facilitate the purpose of the bill, and the United States may subscribe their capital stock from the revolving fund. In such event the President would designate the directors of the corporations, who would hold and vote the capital stock for the exclusive benefit of the United States.

Only a brief survey is required to see that enormous powers are vested in the President, and it is presumed that he will designate certain individuals to exercise these powers for him. Indeed the bill provides for the designation of officers or agents who shall act for the President. In the appointment of these agents will lie the ultimate success of the measure. This was one of the points that caused much discussion over the original House bill which provided for a Minerals Administrator comparable to the Food and Fuel Administrators. The present bill does not contemplate such an official, but there are others that must be appointed, and in their selection the President will have an opportunity to display good judgment. The mining and metallurgical industries have developed some excellent executives and there should be no difficulty in finding good men to fill such places as may be created.

The minerals and metals in the interest of which the bill is drawn comprise a formidable array beginning with antimony and ending with zirconium. In order to meet emergencies, provision is made to include "such other rare or unusual elements" as to which there may be a present or prospective shortage. It remains to be seen whether the assumed need for the bill exists. We believe from many reports received at this office that some federal authority is needed to insure adequate production of certain materials, and in our opinion the desired result should be accomplished by this bill.

## Sidelights on the Exposition

THE Chemical Catalog Co. of 1 Madison Avenue, N. Y., has a busy exhibit on the main floor, and although it has only copies of a single book to show, the visiting public displays a lively interest in it. The purpose of the book is to tell, in convenient form, the names of all the makers and producers of chemicals and chemical apparatus in the country. Publication began in 1916 with an issue of 8500 copies of a book of 205 pages each. In 1918, 10,200 copies were printed and each volume contains 578 pages. The chemical names of materials are given and, as far as possible, trade names are also set forth, while underneath each product or thing indicated is recorded the name and address of every producer in the United States, so far as diligent search may bring it out. Proper cross references serve the purpose of added elucidation and avoid unnecessary repetition as well.

The book is loaned without charge for one year to professors, consulting chemists, chemical engineers, works managers, manufacturers and others comprising a list of such as may have actual use for it as an aid in buying. To others it is sold at the price of five dollars per copy.

A list of technical books is given at the end with descriptive digests and information as to author, publisher and price.

That big Hough patent nitrator which the Buffalo Foundry people show is only their medium size, says Mr. Hough. If used for TNT it takes a charge of 25,000 lb. of mixed acid and 2500 lb. of toluene. The 2500 lb. of toluene is run into the acid in 30 minutes and owing to the spray arrangement and the circulation of the acid, every pound of the hydrocarbon meets 3500 lb. of acid. The volume of the nitrating body keeps down the temperature while the flow of the whole over the cooling coils provides that a variation of not over one-half deg. C. takes place between the point of contact of hydrocarbon and acid and the center of the machine.

As the toluene is injected in, the temperature rapidly rises to 50 deg. C. and it is maintained at this point by control of water in the coils, thus producing dinitrotoluene in the first instance—i.e., in the initial half-hour. The cooling water is then shut off and the heat of the reaction carries the temperature up to the "cooking stage," or about 110 deg. C. In three hours more, or within three and one-half hours from beginning the operation, the process is complete and there is produced about 5300 lb. of TNT or, roughly, 85 per cent of the theoretical yield.

Water is sucked and not driven through the cooling coils and litmus indicators are placed at the outlet of each. Then, if a coil leaks, the acid gets into the water and shows itself immediately, whereupon the offending coil may be shut off and no serious harm is done. If the water were driven through the coils and a coil should leak, the water would go into the acid and play the deuce with the reaction. And there would be no indicator to tell the story. Perfectly reasonable, but rather clever, we think. When the machine is set up it is insulated with three inches of asbestos.

The temperature control enables a great variety of

nitrating processes to be carried on. There is no stuffing box or bearing within the machine. And over 30,000,000 lb. of TNT have been successfully made in several of these apparatus within the past two and one-half years.

\* \* \*

The General Electric Co. has on exhibition some handsome specimens of ferro-zirconium and ferro-chrome-zirconium which they have lately developed with gratifying success.

They show also as a novelty a water japan which should cheer the hearts of the fire insurance men. The japanning ovens of many manufacturing establishments are their danger spots for it is here that fires may get beyond control of the sprinkler system. To this is added the explosion hazard of great quantities of vaporized hydrocarbon or carbohydrate japan solvent mixed with air. The new japan base is a colloid in which the disperse phase is an asphalt and the continuous phase an animal or vegetable oil. By reaction with an alkali a portion of the continuous phase is saponified, whereupon the soap functions as an emulsifying agent. Then, on addition of water, an emulsion is produced in which water is the continuous phase and the japan base the disperse phase. Droplets of the latter are negatively charged and adhere to the positively charged metal in a practically anhydrous state. After baking, the japan is adherent and insoluble in water. Before baking, the japan may be applied with a brush or articles may be dipped in the emulsion, heated to the boiling point of water to give it the proper consistency.

\* \* \*

We have yet to learn of anybody who has worked with Dr. Allen Rogers who did not grow to like him. The Pratt Institute boys who have taken his course in industrial chemistry hover about him whenever they get a chance after they have graduated, and men who have been associated with him on committees or otherwise are likely to respond, if asked to name a good man to undertake a task that requires reasonableness and intelligence and the avoidance of trouble, "Can't you get Allen Rogers?" Now he is in the army in the Chemical Warfare Service, with the slim waist and springy step that they all seem to achieve; and he has a gold leaf on each shoulder, because he is Major Rogers withal, connected with the Relations Section. His name is on the top of a paper given out by the Chemical Warfare Service and under it are recorded the following activities:

The allocation of enlisted men after the war.

Answers to appeal for advice from chemists and from manufacturers.

Transfers of men in the service on indefinite furlough, which is divided under two heads: those not formerly employed where they are needed and those that were.

Deferred classification of chemists and skilled workmen.

Any one of these problems looks to us like a man's job, and if Uncle Sam had come around to ask our advice as to a good man to look after these things; somebody with a heart and a sense of humor and a head that doesn't swell up or run away or topple over, we should have said, as we have said before; "Can't you get Allen Rogers?"

## The Ferro-Alloys\*

A Brief Description of the Manufacture, Properties and Uses of the Alloys of Iron with Manganese, Silicon, Aluminium, Chromium, Tungsten, Molybdenum, Vanadium, Titanium, Boron, and Uranium

By J. W. RICHARDS†

**A**LARGE industry has grown up within the last fifty years, most of it within the last twenty-five years, which furnishes to steel makers alloys of iron with some of the rarer metals, in order to introduce these rare metals into steel. Such alloys are known as ferro-alloys, because they all contain iron (ferrum); some of them, however, contain more of the rare metal than iron. They were originally made in crucibles, cupolas or blast-furnaces, but are now made principally in electric furnaces, and their manufacture is one of the principal electric-furnace industries.

They are of great importance to the steel industry. The steel maker uses them for one of two purposes: (1) As reagents to take oxygen out of melted steel and thus insure sound solid casting (ferromanganese, ferrosilicon, ferroaluminium); or (2) to put into the steel a small or large percentage of the rare metal (ferromanganese, ferrochromium, ferrotungsten, ferromolybdenum, ferrovanadium, ferrotitanium, ferrouranium, ferroboron).

Let us discuss briefly these two uses. Melted steel, just before taking from the furnace, always contains some oxygen dissolved in it (like the dissolved gas in charged soda water). If this is not removed, the casting made is more or less unsound from cavities or blowholes. The addition of a small amount of a metal with a high affinity for oxygen removes this element and makes the casting sound. Manganese (1 per cent or less) is the cheapest and most generally used reagent for accomplishing this; silicon (2 per cent or less) is more powerful but also more expensive, and is often used to supplement the action of manganese; aluminium (0.1 per cent or less) is still more powerful and still more expensive, and is used in very small quantities as a final addition to complete the action of the manganese and silicon. All steel makers use one, two or all three of these reagents; manganese and silicon in the form of ferro-alloys, aluminium more often as the pure metal, but ferro-aluminium is sometimes used.

The second use is to make special steels, that is, steels containing such quantities of the rare metal as give to them properties different from plain carbon steels deoxidized by manganese, silicon or aluminium. Thus we may make manganese steel by putting in 12 to 14 per cent of manganese making a very tough, hard steel such as is used in mining and grinding machinery, burglar-proof vaults etc.; chromium (2 to 4 per cent) makes a very hard tool steel; tungsten (15 to 25 per cent) makes high-speed tool steel, which cuts iron while

red-hot; molybdenum (6 to 10 per cent) has powers similar to tungsten, and is also used in steel for lining large guns. Vanadium ( $\frac{1}{10}$  to  $\frac{1}{2}$  per cent) makes very strong steel which resists shock extremely well, as when used for automobile axles; titanium, uranium and boron impart valuable properties not so easily described. Every one of these materials is used for producing some specific result which is not produced by any other; sometimes combinations of two, three or four are used in one steel, producing a particular combination of special properties for some special purpose. Some of these materials cost \$5 per pound, and the special steels produced cost up to \$2.50 per pound, but their particularly valuable properties justify the expense. The value of these special steels to the industries, and particularly for military purposes, is very great, so great that the supply of ferro-alloys for their manufacture is an important factor in winning the war.

### FERROMANGANESE

This is the oldest of the ferro-alloys. Its manufacture was begun about 50 years ago. It was first made in crucibles, has for a long time been made in blast-furnaces, but is now being produced in many places in electric furnaces. It is made with 30 to 85 per cent manganese, 3 to 5 per cent carbon, a little silicon and the rest iron. The rich grades, 75 to 85 per cent, are preferred by the steel maker, but they require rich manganese ores for their manufacture. The United States has very little rich manganese ore, but large quantities of low-grade ores; one of the present burdens of the steel maker is to use low-grade ferromanganese, in order that we may not have to use ships for importing the high-grade ores from Brazil.

The usual manufacture in blast-furnaces is wasteful of both fuel and manganese; the furnace must be run hot and slowly, with very hot blast in order to reduce the manganese oxide ore as completely as possible and not waste manganese in the slag. Yet, in spite of all efforts, from 15 to 25 per cent of the manganese going into the furnace escapes reduction and is lost in the slag. This waste of fuel and manganese has led to the use of the electric furnace, in which fuel is required only as a chemical reagent and not to produce heat, thus saving about two-thirds the fuel requirements of the blast furnace, while the higher temperature available causes the extraction of manganese to reach 90 per cent, i.e., slag losses to be down to 10 per cent or less. Against these economies must be set the considerable expense for electric power and the smaller scale on which the furnaces run. At the present high prices of coke and manganese ore, and in view of the scarcity of manganese and the high price of ferro-

\*A paper read at the Fourth National Exposition of Chemical Industries, New York, Sept. 27, 1918.

†Professor of Metallurgy, Lehigh University; Secretary, American Electrochemical Society; Member, U. S. Naval Consulting Board.

manganese, the electric ferromanganese industry is able to exist and make large profits. Whether it can do so when normal conditions return, after the war, is questionable; it is to be hoped that it will be able to do so, because of the economy which it undoubtedly possesses in regard to fuel and manganese.

Steel producers use ferromanganese particularly for making the low carbon or soft steels, because they can thus introduce the required manganese for de-oxidation without putting in considerable carbon. For higher carbon steels spiegeleisen (15 to 20 per cent manganese), a cheap blast-furnace alloy, can be used, and is being used at present wherever practicable, in order to save ferromanganese. The best practice with either spiegeleisen or ferromanganese is to melt them in a small electric furnace, and tap from it the required weight to be added to the heat of steel. The melted alloy mixes quicker with and reacts more actively upon the melted steel, while less of it is necessary because less is oxidized by the furnace gases. The saving in manganese by the use of the electrically-melted ferro is alone sufficient to justify the expense of melting it in an electric furnace, while better and more homogeneous steel is produced.

#### FERROSILICON

This alloy may run 15 to 90 per cent silicon, but the most commonly used is the 50 per cent grade. It is made from ordinary silica (quartz or sand), reduced by carbon in the presence of iron ore or scrap iron. The blast furnace is able to make only the lowest (15 per cent) grade, because silica is exceptionally difficult to reduce, and under conditions which would reduce 99 per cent of the iron ore in a furnace, or 75 per cent of the manganese ore, only 15 to 20 per cent of the silica present can be reduced, and only a low-grade silicon alloy produced. The higher grades must all be produced in the electric furnace.

The raw materials are ordinary silica, the most abundant metallic oxide on the earth's surface, iron ore or scrap iron (iron or steel turnings or punchings), and coke. Electric furnaces up to 10,000 hp. have been operated on ferrosilicon (50 per cent grade). At the high temperature required, a not inconsiderable proportion of the reduced silicon vaporizes, and burns outside the furnace to a white silica smoke. This can be largely prevented by skillful furnace supervision. In normal times, the 50 per cent alloy sells at \$45 to \$50 per ton, which is a low price for an alloy so difficult to produce.

Steel producers use ferrosilicon principally for the great activity with which the silicon removes dissolved oxygen from the steel. It is about four times as active as manganese in thus reducing blow-holes and producing sound castings. It is usual, however, to use manganese first, to do the bulk of the deoxidation, and silicon afterwards to finish up the reaction more completely. It is particularly useful in making sound steel castings which are cast into their ultimate form and do not have to be worked into shape, because a slight excess of silicon may make the steel hard to forge or roll, whereas an excess of manganese does not have so bad an effect on the working qualities. A particular kind of steel called silicon steel carries 1 to 2 per cent of

silicon and yet forges well; this would be classed as a special steel.

The ferrosilicon industry has attained large proportions in countries where electric power is cheap, particularly therefore in Switzerland, the French Alps, Norway, Canada, and parts of the United States. Under present conditions it is even profitably run where electric power is relatively dear, as at Anniston, Ala., and Baltimore, Md. It is a large, interesting, and rapidly growing industry.

#### FERRO-ALUMINIUM

This alloy, with 10 to 20 per cent of aluminium, was made in the electric furnace and used in considerable quantity in steel about 1885-88, but was displaced by pure aluminium as the latter became cheaper. Aluminium is about seven times as powerful as silicon and twenty-eight times as strong as manganese in acting upon the oxygen dissolved in steel; therefore only minute quantities are necessary, say one ounce up to a maximum of one pound of aluminium per ton of steel. Its use gives the finishing touch to the de-oxidation of the steel.

About 1885 the Cowles brothers, operating the first large electrical furnaces run in America, at Lockport, New York, made and sold considerable quantities of ferroaluminium, selling the aluminium in it at the rate of about \$2 per pound, while the pure metal was then costing \$5. When, a few years later, pure aluminium sold for 50 cents per pound, the steel makers turned to using the pure metal instead of ferroaluminium, and at the present time aluminium is so used in practically every steel works in the world.

There seems to me a distinct opportunity for makers of ferro-alloys to revive the manufacture and sale of ferroaluminium. Such great advances have been made in the construction and operation of large electric furnaces since 1890, and so much experience has been had in reducing the difficult oxides to ferro-alloys, that the production of 50 per cent ferroaluminium at say \$100 per ton may be a distinct electric furnace possibility. That would furnish the contained aluminium at about 10 cents per pound, as against 30 cents for the commercial aluminium now used. The alloy should be broken up small before using, and thrown in the runner or on the bottom of the ladle, in order that the melted steel may quickly dissolve it as it runs into the ladle.

Such ferroaluminium would require bauxite with iron ore or scrap iron, for its manufacture, but there are large deposits of low-grade bauxite rich in iron, in Southern France, which could be reduced directly to the alloy without any additions, and thus furnish very cheap raw material for the operation.

In conclusion, ferroaluminium is not now being made, but its electric furnace production is a real possibility.

#### FERROCHROMIUM

Ferrochromium is used for making what is familiarly but erroneously called "chrome steel." It makes steel exceedingly hard. Very hard cutting tools, and armor plates to resist projectiles, are made of it. Only 2 to 4 per cent of chromium may be used.

Several grades are made in the electric furnace, depending on the per cent of chromium (25 to 75), and

the content of carbon (2 to 8 per cent). This alloy takes up carbon so actively in the furnace that it has to be treated subsequently to remove the carbon down to what can be endured by the steel into which it is introduced.

The raw material for its manufacture is chromite, an oxide ore of both chromium and iron. If this is mixed with carbon and smelted in the electric furnace it reduces directly to ferrochromium alloy (often misnamed "ferro-chrome"), and highly saturated with carbon (6 to 10 per cent). Steel makers want lower carbon than this, so the alloy is re-melted with more chromite in another furnace, and the excess of carbon oxidized out. The low-carbon alloy sells for 2 to 3 times the price of the high-carbon crude material.

The cutting off of importations of high-grade chromite ore from Asia Minor has led to intense prospecting in the United States. Fair material has been found in many places, and at present our country is nearly independent of foreign sources of the ore.

#### FERROTUNGSTEN

Tungsten (also called wolfram) imparts curious and valuable properties to steel. A small amount (2 to 5 per cent) has been used for half a century or more, to make the steel self-hardening; that is, a tool of this steel need only be let cool in the air, and it becomes hard without the ordinary quenching or chilling operation. Larger proportions (10 to 25 per cent) make a steel which stays hard even when red hot. A tool of this material can be run so fast on a lathe, for instance, that it gets red-hot from the friction and work, yet keeps hard and keeps on cutting. It is called high-speed tool steel, and its use alone has more than doubled the output capacity of the machine shops of the world.

The ore used in either wolframite, a black oxide of iron and tungsten, or scheelite, a white oxide of calcium and tungsten. It is found in considerable quantities in Colorado, and some other Western States, and imports of this ore have not been necessary during the war. In this respect we are much more favorably situated than the European nations. A plentiful supply of tungsten ore may indeed be regarded as a large factor in the production of cannon and fire-arms and all kinds of machinery, and therefore a considerable factor in winning the war.

#### FERROMOLYBDENUM

Molybdenum has only recently come into large use in steel. Its action being somewhat similar to that of tungsten, scarcity of the latter metal, particularly in Europe, has led to the manufacture of ferromolybdenum on a comparatively large scale.

The ores are widely distributed but not very plentiful. Molybdenum sulphide, molybdenite, looks almost exactly like shiny graphite but it is a shade lighter in color and nearly twice as heavy. It occurs usually as flakes in granite rock and might easily be mistaken for graphite. Lead molybdate, wulfenite, is a compound of lead and molybdenum oxides, a very prettily crystallized yellow to red mineral in thin square plates. It occurs abundantly in a few lead mines in the West. It is usually first treated to extract its lead, and the residue then worked for molybdenum. The sulphide

used to be roasted to molybdenum oxides, and this reduced by carbon in the presence of iron ore or scrap iron in an electric furnace. It is now smelted directly in the electric furnace with carbon and a large excess of lime along with iron ore or scrap iron. Ferro with 50 to 60 per cent of molybdenum is tapped from the furnace like other ferro-alloys, but with molybdenum up to 80 per cent the alloy has such a high melting point that it cannot be tapped out without freezing; it is necessary to make a furnace full of this alloy and then let the furnace cool down and take it apart, taking out a large mass of solidified alloy; the furnace is then rebuilt.

The large use of molybdenum in steel has been so recent that not much has been made public about it. Rumor says that the large German guns which bombarded Liege (the "Black Berthas") were lined with molybdenum steel (6 to 7 per cent) to increase their resistance to erosion. It seems certain that Germany drew considerable supplies of molybdenite from Norway to compensate for shortage of tungsten for high-speed tool steel. Parts of guns, gun carriages, motors, automobiles, have also been made of molybdenum steel of most excellent quality. Canada has been especially active in the manufacture of ferromolybdenum steel, most of which is exported to Europe. This alloy is therefore another valuable war material.

#### FERROVANADIUM

Without vanadium the modern automobile or auto-truck would be a much weaker machine. When steel is desired to withstand the heaviest shocks and vibration, nothing is quite so effective as adding vanadium. This is another comparatively rare metal, found principally in the radium ores of Colorado and as a black sulphide on the highlands of Peru. The canary yellow Colorado ore is treated for radium, and the residues for vanadium and uranium. The U. S. Government (Bureau of Mines) operated this process for the radium supply. The black ore of Peru is rich and unusual; it is a sulphide with some asphaltic matter, and it is roasted to the condition of iron-vanadium oxide before reduction. The oxides are best reduced by metallic aluminium. This is the well-known thermit (Goldschmidt) method of reduction. Electric furnace reduction by carbon is not advantageous because of the large amount of carbon taken up by the alloy; powdered silicon is therefore put into the charge as the reducing agent, together with iron, lime and fluorspar, and then a 30 to 40 per cent vanadium alloy is obtained with seldom over 1 per cent of carbon, a very desirable composition (R. M. Keeney).

Only small amounts of vanadium are necessary to improve steel; 0.1 to 0.4 per cent are the usual quantities. This is fortunate because the vanadium costs \$5 per pound and over. Metallurgists suspect that part of the improvement of the steel may be due to the vanadium combining with and removing nitrogen dissolved in the melted steel. This is probably true, yet some advantage undoubtedly must be ascribed to the final vanadium content in the steel; both avenues of improvement function. Steels thus treated are unusually resistant to shock and alternate stresses, making them very useful for axles, cranks, piston-rods, and such severe service.

## FERROTITANIUM

Titanium is an abundant element in nature. It occurs in immense amounts as a double oxide of titanium and iron, known as ilmenite, or titanic iron ore. This ore can be reduced directly by carbon in electric furnaces to ferrotitanium. The reduction proceeds easier if some aluminium is put in as a reducing agent, but this is expensive and unnecessary. The alloy running 15 to 25 per cent titanium is sold for use in steel as a refining agent to remove oxygen and nitrogen. Thousands of tons of steel for rails has been thus treated, the tests showing considerable improvement in the mechanical properties by the use of quite small amounts (0.10 to 0.20 per cent) of titanium.

## FERROBORON

This is another alloy whose valuable qualities have not yet been entirely determined. Boron is the metallic base of borax, which is a sodiumboron oxide. Borax is very difficult to reduce to the metallic state. Another raw material, not so abundant, is colemanite, containing lime and boron oxide. Many attempts have been made, none very successfully, to reduce this with iron oxide to ferroboration. The American Borax Co. offered a prize, for several years, for a process which would accomplish this. Boron oxide occurs rarely in nature, but it can also be manufactured from borax and colemanite. When the oxide is obtained, this can be combined with iron oxide and the resultant boron-iron compound reduced by carbon in the electric furnace to ferroboration. Small quantities of this alloy have thus been manufactured.

Experiments on steel have shown that ferroboration acts somewhat similarly to ferrovanadium. Experiments in France showed remarkably strong and tough steels were thus made, using 0.5 to 2 per cent of boron. The results have not been properly followed up, partly on account of the difficulty in getting ferroboration; no one, as yet, has taken up its regular manufacture and steel makers can hardly be blamed in these stirring times for not having as yet thoroughly explored its possibilities as an addition to steel.

## FERRO-URANIUM

This is the latest of the ferro-alloys to enter the lists. Uranium is a very heavy and, chemically, very active element. It is found very scarcely as a black oxide, the mineral pitchblende—the mineral in which radium was first discovered. It is found more abundantly in the Colorado radium ore, a bright yellow oxide and silicate of vanadium, uranium and lime. After extracting the radium and vanadium, the uranium remains in the residue as a by-product, usually as a soda-uranium compound. This is treated so that uranium oxide is obtained, and this can be reduced by carbon in an electric furnace in the presence of iron ore or scrap iron, to ferrouanium (30 to 60 per cent). The recovery of uranium is not high (50 to 70 per cent) the rest being lost in the slag. Mr. R. M. Keeney has recently described these processes in detail, for the first time in the August *Bulletin* of the American Institute of Mining Engineers.

The results of tests showing the influence of uranium on steel are not yet completely known. Some firms have

claimed for it wonderful strengthening power and resistance to shock. The subject is still receiving expert attention from steel makers, and valuable results are confidently expected.

## CONCLUSION

The ferro-alloys are exceedingly important materials to the steel maker, either in the making of ordinary steel or for producing special alloy steels. They are indispensable to the steel industry. They are important factors in producing both ordinary and fine steels, and therefore in winning the war. The country well supplied with them has a great advantage over the country in which they are scarce. They are deserving of all the expert attention which they are receiving from the War Industries Board, the steel makers, and the economists. The possession by the United States of large supplies and resources in the ferro-alloy line, may be one of the important factors in determining the quick ending of the war.

## Spelter Specifications

The percentage of impurities in the four commercial grades of spelter have been compiled by C. E. Siebenthal of the U. S. Geological Survey from the following specifications:

1. Am. Soc. Test. Mat. Proc.; vol. 11, pp. 147-149, 1911: Adopted August 21, 1911.
2. Am. Soc. Test. Mat. Proc.; vol. 16, pp. 583-589, 1917. vol. 17, pp. 180-181, 1917.
3. Navy Department Specifications, 47Zld, June 1, 1917.
4. U. S. Army, Ordnance Department Specifications, Revised March 7, 1918.
5. Navy Department Specifications, 47Zlb, Nov. 1, 1913.
6. New York Metal Exchange Specifications; American Metal Market, August 31, 1916.

## Speeding Up Metallurgical Analysis

Pertinent Comments on the Analyst's Part in Production—Selection of Methods That are Rapid and Accurate—Arrangement of the Laboratory is Important Factor

BY HAROLD C. PARISH

IN THESE days of intensive production it becomes not only a necessity but the patriotic duty of every chemist engaged in analytical work to produce results in the shortest possible time. In order to do this he must make use of every legitimate short-cut and so plan his work that every moment is utilized to the best advantage. In laboratories where the nature and volume of work received each day is comparatively uniform and where the work can be reported in the order received, this is a comparatively simple matter. In laboratories where this is not true, the problem becomes more complicated. In many laboratories the chemists are often required to report the work received on a given day ahead of that coming in the previous day. This so-called rush work upsets the routine considerably and tends to decrease efficiency.

There are several factors which are involved in the problem of speeding up metallurgical analysis, chief among which are the following:

1. Convenient and efficient arrangement of hoods, benches, sinks, apparatus, and chemicals.
2. The proper preparation of samples.
3. Selection of such methods of analysis as will give the required degree of accuracy in the shortest space of time.
4. Planning of the work in such a way as to make every minute count.
5. Handling of the common laboratory manipulations involved in such a way as to produce maximum efficiency.

### ARRANGEMENT OF THE LABORATORY

It will be obvious that it is impossible to offer other than very general suggestions for the laboratory layout on account of variations in conditions in different laboratories as regards amount of available space and facilities. It should be the aim to have the arrangement as compact as possible and designed to save steps. Whenever possible, it will be found convenient to have the hood situated back of the worker. In any event, it is essential in a properly arranged laboratory to have hoods centrally located and of ample proportions. This is equally true of benches, sinks and balances. Obviously, the balances should be protected from laboratory fumes. The author has found it convenient to place standard solutions on a shelf above the working bench and to have the bottles or carboys containing these solutions connected with their respective burettes in such a way as to feed by gravity.

The burette stands may be set back on a bench out of the way. There should be sufficient cupboard and drawer space underneath the benches to contain apparatus in constant use. Small reagent bottles containing ammonia, the mineral acids and any other chemicals in frequent use are best located on a small shelf above

the working bench and plainly labeled. Stock reagents should also be kept near at hand. Space should be provided for as much permanent apparatus as possible. Probably as much valuable time is lost in many laboratories in setting up and dismantling apparatus every time certain determinations are made requiring special apparatus as in any other way.

### PREPARATION OF SAMPLES

It is obvious that the condition of samples has considerable influence upon the speed of weighing and the solution of these samples in acids. It is a very difficult matter to weigh or dissolve coarse samples rapidly. Furthermore, the accuracy of many methods depends upon the comparatively fine division of the samples. For sampling soft white metal alloys a coarse rasp or a hack saw gives a very satisfactory sample. A hack saw may also be used for sampling copper, brass or bronze. These latter alloys, as well as iron and steel, may also be sampled to good advantage with a flat or a twist drill which has the sharp edge of the lip slightly dulled by grinding. This treatment of a twist drill eliminates coarse curly drillings. Obviously, care should always be taken to obtain representative samples. In determining carbon in steel or iron the author uses only those drillings which pass a 20- and remain on a 60-mesh sieve. In this way very excellent results may be obtained.

### SELECTION OF METHODS OF ANALYSIS

It is a deplorable fact that a large number of chemists are using the longer methods of analysis when results of equal and sometimes greater accuracy could be obtained by the use of shorter ones. Every chemist should be alive to this vitally important phase of the problem and always be on the lookout for shorter methods of analysis or means of eliminating unnecessary steps in procedures already in use. If he is not certain of the accuracy of a method new to him, he should check it thoroughly against one known to be reliable. Published methods of procedure are too often followed mechanically without a thought as to whether or not they can safely be shortened. A little experimental work would often point out modifications which would not interfere with the accuracy of the analysis. Maximum accuracy required plus maximum speed should be the aim of every analyst.

It may be of interest to mention methods used in iron and steel analysis which seem to give this desirable combination. No attempt will be made to go into detail except in one or two instances, as most of the procedures are so well known by name that no description is necessary. Shorter methods have been tried in many instances, but have not been adopted because they did

not prove reliable. Some readers may be using procedures which are still shorter and give equally accurate results. If so, they should certainly publish them in the interests of efficiency if they have not already appeared in the literature. The following is a list of methods used in this laboratory in steel analysis.

*Silicon.* Drown's method.

*Manganese.* Bismuthate-arsenite.

*Phosphorus.* Alkalimetric titration of the ammonium phosphomolybdate.

*Carbon.* Direct combustion at 1000 deg. C. and absorption of  $\text{CO}_2$  in 12-mesh soda-lime containing 15 per cent water.

*Sulphur.* Evolution method. Precipitation of  $\text{H}_2\text{S}$  as cadmium sulphide and titration with standard iodine solution.

*Chromium.* A further modification of "Barba's Modifications" described in Blair's "Analysis of Iron."

*Nickel.* A modified cyanide method.

*Vanadium.* Johnson's method, titrating with ferrous ammonium sulphate, using potassium ferricyanide as an indicator.

*Tungsten.* Rapid method described in Blair's seventh edition, page 204.

A description will be given of the methods mentioned above for chromium and nickel. A few suggestions for saving time in operating some of the other methods may be helpful to someone.

*Carbon.* The only point that suggests itself regarding the determination of carbon is that time can be saved by weighing all of the determinations to be made for the day in one sitting. In this way there will always be a sample ready to put into the furnace as soon as another one is taken out and there will be less interference with other work.

*Silicon.* The method of Drown calls for the solution of the sample in a mixture of nitric and sulphuric acids, evaporation to the evolution of  $\text{SO}_2$  fumes, solution of residue in water or dilute HCl, filtration of  $\text{SiO}_2$ , ignition and weighing. In this determination the  $\text{SiO}_2$  can be filtered much more rapidly if the residue is dissolved as soon as possible after evaporating to fumes and filtered immediately while still hot. If the washing of  $\text{SiO}_2$  with dilute HCl and hot water is sufficiently thorough, it should not be necessary to make an evaporation with HF after ignition and weighing. If the  $\text{SiO}_2$  is not pure white, however, after ignition, this evaporation must be resorted to. One weight can be avoided by carefully brushing the  $\text{SiO}_2$  into balanced watch-glasses instead of weighing the crucible.

*Manganese.* The determination of manganese is carried out just as described in Blair's seventh edition, page 122, up to the point of titration, when standard sodium arsenite is used as described in Lord & Demorest's "Metallurgical Analysis" under the "Bismuthate-Arsenite" method. A porous alundum thimble is used for filtering the solution by suction previous to titration.

*Phosphorus.* The alkalimetric determination of phosphorus in iron and steel is equally as accurate as the Emmerton process of reducing a solution of the ammonium phosphomolybdate with zinc and titrating with  $\text{KMnO}_4$ , and everyone who has used both methods will agree that much time can be saved by using the former.

*Sulphur.* Where many sulphur determinations are made it is best to have a sulphur rack built and connected with the gas supply as a permanent laboratory fixture. The number of determinations which it should accommodate at one time depends, of course, upon the volume of work handled each day. The one the author uses carries ten.

*Chromium.* Barba's modification, referred to above and described on page 197, Blair's seventh edition, calls for the addition of a comparatively large excess of  $\text{KMnO}_4$  to oxidize chromium after the solution and oxidation of a 1½-gram sample with  $\text{HNO}_3$ . This excess is destroyed with ammonia, the solution again acidified with  $\text{H}_2\text{SO}_4$ , boiled,  $\text{MnO}_2$  filtered off, aliquot taken representing 1 gram and the solution titrated with standard ferrous ammonium sulphate and potassium permanganate.

The author has for some time used a modification of this method which has served for several hundred determinations and been found to give results equally accurate and to be more rapid. A 1-gram sample is dissolved and oxidized with nitric acid, exactly the same as described by Blair. After the oxidation the solution is then diluted to approximately 100 cc., brought to a boil, and while boiling, a saturated  $\text{KMnO}_4$  solution is added a few drops at a time from a pipette, the solution being warmed between each addition, until a permanent precipitate of  $\text{MnO}_2$  is obtained. The solution is then boiled for 15 or 20 minutes, or until upon removal from the application of heat the precipitate settles rapidly leaving a clear yellow supernatant liquid free from pink tints. The solution is cooled, filtered and titrated as usual with ferrous ammonium sulphate and potassium permanganate.

If vanadium is desired, the pink produced by the  $\text{KMnO}_4$  should be just destroyed with the ferrous ammonium sulphate solution, exactly 2 cc. of a 2 per cent potassium ferricyanide indicator added and the vanadium titrated with ferrous ammonium sulphate to the destruction of yellow tints, according to Johnson.

*Nickel.* Several years ago Mr. Arthur G. Carman, formerly connected with this laboratory, worked out a modification of the cyanide method which the author believes to be the most rapid method in use for this determination. The method is carried out as follows:

Dissolve 1 gram of steel drillings in a 400-cc. beaker with 20 cc. 1:1 HCl. When action ceases, add 10 cc. of 1:1  $\text{HNO}_3$ . Boil until the red fumes have been driven off and the carbon is completely destroyed. Add 100 cc. of citric acid solution, dilute to 300 cc., and add with a pipette exactly 5 cc. of standard  $\text{AgNO}_3$  solution. Now add just sufficient ammonia to destroy cloudiness, then 2 cc. of KI solution and titrate with standard KCN solution to the disappearance of turbidity. This titration is best done by transmitted artificial light, placing the beaker on a piece of black glazed paper. The end point is easy for an experienced operator to detect and is not reached as long as a drop when striking the solution produces a spot clearer than the solution around it. As soon as the end point is reached all turbidity will have disappeared. If it is thought that the end point is passed, add a measured amount of  $\text{AgNO}_3$  solution until turbidity just appears. It is best to have another beaker containing a solution

to be titrated, to which no  $\text{AgNO}_3$  has been added, placed beside the one being titrated so as to have a clear solution for comparison. If the citric acid was dirty, the solution will be cloudy and should be filtered before the  $\text{AgNO}_3$  is added.

#### *Solutions:*

*AgNO<sub>3</sub>.* Dissolve 2.885 grams of C.P.  $\text{AgNO}_3$  in water and dilute to 1000 cc.

*KI.* Dissolve 50 grams of C.P. KI in 250 cc. of water.

*Citric Acid.* Mix 380 grams of C.P. ammonium sulphate, 270 cc. of concentrated ammonia, 1430 cc. of water, and 240 grams of citric acid.

*KCN.* Dissolve 8.85 grams of pure, or 9.03 grams of 98 per cent KCN and 10 grams of KOH in water and dilute to 2000 cc.

*Standardization.* The KCN solution is most conveniently standardized against a U. S. Bureau of Standards 3.50 per cent nickel steel, the same procedure being followed as above. An additional titration must be made in order to obtain the relation between  $\text{AgNO}_3$  and KCN. This is accomplished in the solution after titration for standardization by adding exactly 10 cc. standard  $\text{AgNO}_3$  to solution and running in standard KCN to disappearance of turbidity. One-half of the amount of KCN required is to be subtracted from the amount used in each determination.

#### *Notes:*

1. The presence of sulphates is necessary to obtain a sharp end reaction.  $\text{AgI}$  is soluble in a large excess of  $\text{NH}_4\text{OH}$ , so care should be taken to have the solution only slightly alkaline with  $\text{NH}_4\text{OH}$ .
2. If the titrated solutions are allowed to remain in open beakers for some time, a white film forms on the surface but no account is to be taken of it.
3. When chromium is present in appreciable amounts the same procedure is followed, except that it may be necessary to add a little more citric acid solution in order to hold the chromium in solution when ammonia is added.
4. The  $\text{AgNO}_3$  solution used should not be stronger than that indicated above, for when a stronger silver solution is used, the  $\text{AgI}$  instead of forming a turbid solution settles out as a curdy precipitate which does not readily react with the cyanide. If a ferro-nickel is being analyzed a stronger solution of KCN should be used.
5. Such elements as V, Cr, W, Mo or Mn do not interfere even when present in large amounts in the sample. Copper, however, is titrated with KCN but is usually present in negligible quantities. If its presence is suspected, nickel should be determined by the dimethylglyoxime method.

*Vanadium.* This method will be found described in Johnson's "Chemical Analysis of Special Steels," also Lord & Demore's "Metallurgical Analysis."

#### NON-FERROUS ALLOYS

The number of different methods of analysis used in non-ferrous alloy work is so great that it would be practically impossible to deal with them comprehensively in this paper. The author uses electrolytic methods for determining copper, lead and zinc in brass and bronze where the lead does not exceed 10 per cent. If the alloy contains more than 10 per cent, the lead

is determined as  $\text{PbSO}_4$ . Some means of agitating the solutions when electrolysis is in progress will aid in obtaining quick results. Rotating anodes or cathodes may be used for this purpose, also solenoids, or even compressed air. Where allowable, much time can often be saved by taking some element by difference after all other elements present have been carefully determined. It is perfectly legitimate and accurate, providing the other figures are correct. Whenever determined in this way the fact should be noted in reporting. For instance, in the analysis of Muntz metal, copper, lead and iron may be determined accurately in a very short time. Tin or any other impurities may also be tested for or actually determined quickly. After this is done there is no reason whatever why zinc should not be reported as the remainder, unless for some reason the practice is not allowed. The practice is a dangerous one if not carried out in a conscientious manner. It is never done in this laboratory except with the full knowledge and consent of the client, as some object for reasons best known to themselves. The majority, however, prefer to have it done this way where speed is a factor.

The white metal alloys cover a very large field and include babbitt metals, solders and aluminum alloys. Various types of babbitt metals require different procedures. For instance, tin-base babbitts must be handled in a different way than lead-base babbitts, while those alloys containing more antimony than tin act differently than those in which tin predominates. In fact, the subject is such a broad one that it would be impossible to do it justice in this article. Chemists who are doing this sort of work should always bear in mind the point made above regarding the possibility of using shorter methods of procedure. Get in touch with your fellow chemists and find out what methods they are using. Search the literature also, keeping in touch with the current information. If someone publishes a method which looks reasonable and seems shorter, do not be afraid to try it. If it gives satisfactory results after a thorough trial, adopt it. Many methods with excellent possibilities are condemned after one trial, often when it is not the fault of the method itself, but because the operator had not learned how to handle it properly. Many chemists are using long procedures which have been handed down to them simply because they give accurate results and because they have not the necessary nerve to find out for themselves if a shorter one will prove to be as accurate. If everyone assumed this attitude there would be no progress.

#### PLANNING THE WORK

Here, too, it is difficult to offer any very specific suggestions on account of differences in conditions such as nature and volume of work, whether or not it can be handled in the routine manner, facilities, etc. The first thing to bear in mind in planning the work in a busy laboratory is that every minute must be utilized to the best advantage. It is customary in many laboratories to divide the analyses between several men who always make the same determinations. This seems to be the most efficient way of handling it, and wherever possible it is preferable.

The author has found that it works well to weigh all samples for the day's work at one sitting and to start

them all off as quickly as possible. Those determinations which will need no attention for some time should be started first and others which require considerable attention can be worked in. Moreover, if there are several miscellaneous samples upon which similar determinations are required, these should all be run along together, or at least as many as facilities will allow. It will often prove to be a saving of time to sit down at the beginning of the day and to spend a few minutes merely making plans for the day's work. It will not always be possible to adhere strictly to these plans, but it will help considerably.

There are many ways of saving time in the common manipulations which it may seem superfluous to mention. Still, they are important from the standpoint of speed, and not all chemists make use of them. It is only for such analysts that the suggestions are intended.

There is the question of filtering. One of the first things a chemist usually learns in a laboratory or in college is how to choose a good funnel and how to fit a filter paper into this funnel properly. In spite of this it is surprising how many are careless in this respect and do not seem to realize how much unnecessary time may be lost by slow filtrations. It is not the intention to describe how this should be done, as it is too well known, but merely to call attention to the importance of painstaking in this direction. It is sufficient to say that the filter paper should fit perfectly. Long straight-stemmed 60 deg. funnels work best. They will be found to filter faster if the angle formed by the stem and funnel proper is abrupt, rather than flaring.

The grade of filter paper is also important. A paper of no closer texture should be used than is necessary to hold the precipitate which is being filtered. If possible, a column of liquid should be maintained in the stem of the funnel. This may be done either by gentle pressure on the mouth of the funnel with the palm of the hand or by playing a strong stream from the wash bottle around the upper edge of the filter paper. Many slow-filtering precipitates, such as aluminium hydrate, may be filtered and completely washed in two to three minutes by using suction and a Buchner funnel. It will be found a great time saver in weighing, instead of having the balance adjusted to zero to have it so adjusted that the pointer will swing three divisions to the right. This saves waiting for a swing in both directions. It is obviously necessary to have it swing the same distance before and after the weight.

The use of factor weights in gravimetric work saves considerable time in calculations. In weighing steel samples a magnetized spatula may be used to good advantage in the final adjustment. It will also be of value in steel work to bear in mind the fact that it is a waste of time to attempt to weigh samples for those elements such as sulphur, phosphorus, silicon etc. which are present in small quantities with the degree of accuracy necessary with higher percentages. Much time, also confusion, may be saved by always forming the habit of arranging numbers in order when filtering etc., the lowest number always at the left, or right, as the operator prefers.

#### CONCLUSIONS

It is realized that many of the suggestions which have been offered will seem too obvious to many to war-

rant publication. On the other hand, if a solitary chemist is assisted by anything which has been offered, the paper will be justified. The valuable assistance that can be obtained by keeping constantly in touch with one's fellow workers and by making occasional visits to other laboratories cannot be overestimated. Do not be afraid to admit that someone is doing something in a way of which you have never heard. By doing so you may create a barrier between yourself and valuable information. Do not lose sight of the fact that your knowledge, as well as that of everyone else, is limited; admit it by asking questions. The other fellow will think more of you and tell you more.

Cambridge, Mass.

## A New Method of Microscope Illumination

(Second Paper)

BY ALEXANDER SILVERMAN

IN A NUMBER of papers<sup>1</sup> which have appeared during the past year the writer described a new illuminator for microscopes.<sup>2</sup> The supplementary material here given is presented for the benefit of those already using the device and for others who may be interested.

**The Lamp.**—A new 9-volt, 0.7-ampere daylight (blue glass) lamp has been devised, which will yield 50 per cent more light than the old 6-volt, 0.7-ampere lamp. The illumination is not only better but the terminals of the lamp are closer together so that the filament more nearly approaches a complete circle. Researches which are under way may provide a lamp of still greater light intensity. A new enamel is employed for the reflector to prevent the scaling experienced with the old type.

**The Rheostat.**—A tube resistance with three connecting-posts for 107 v., 112 v., and 118 v. permits of the use of the lamp with the ordinary A.C. or D.C. lighting circuit. A similar device for 220-v. circuits is in preparation. By connecting on a lower voltage tap the light may be increased for photographic purposes.

**Heat Insulation.**—Although the writer has had the illuminator attached to objectives and going constantly for a half hour at a time, no injury was suffered by the objectives. The circular space of about one-quarter of an inch between the holder and the objective permits cold air to circulate between the two. Although the heat radiated and conducted should not prove serious, an effort is being made to lower the temperature of the lamp by reducing the size of the anchor wires. Radiated heat may be cut down by giving the lamp a black coat over the white enamel reflector.

**The Shutter.**—A shutter has been devised which may be slipped into the holder for cutting off the light from one-half of the field. The shutter may be revolved so as to send oblique light from any side to the specimen under examination. This is of value in detecting pearly structure in iron, etc.

**Vertical and Oblique Light.**—The new illuminator may be attached to the microscope without removing the

<sup>1</sup>J. Ind. Eng. Chem., 9:971 (1917). Met. & Chem. Eng., 15:318 (1918).

<sup>2</sup>U. S. Pat. 1,267,287. Can. Pat. 185,233. Other U. S. and foreign patents pending.

vertical illuminator, thus affording a rapid comparison of the effect of vertical and oblique light. Details may be visible under one illuminator which would not appear with the other. For example the interior of small pores and slag pits is usually black under vertical light, while the new illuminator shows depth and the nature of the content if slag or other substances are present.

**Photomicrography.**—Some metallographers are still skeptical because of the low power of the lamp, as they have been accustomed to using arc lamps or powerful nitrogen-filled tungsten lamps.

As has been intimated in earlier papers, definition in ordinary photography is obtained by using a very small aperture and giving a long exposure. The writer's experience has been that excellent photomicrographs are obtainable with the new lamp in a few minutes by removing the eye-piece and that with 8-mm., 16-mm., and objectives of lower power, even 60-mm., clear images are obtained on the ground glass. Even better results may be obtained using a very fine etched ground glass and rubbing the dull surface with a little vaseline, afterwards removing as much of it as possible with a dry cloth. Fine definition is possible with highly polished steels, brasses, bronzes, etc. Even ball bearings give a clear image on the treated ground glass.

The writer desires to express his appreciation of the valuable suggestions made by numerous scientists who are doing pioneer work in this new field of micro-illumination.

University of Pittsburgh.

## Electrolytic Refining of Antimony

BY Y. C. WONG

LOW grade antimony ores are not a commercial source of antimony at the present time, although for over thirty years many chemists have from time to time, chiefly under the stimulus of war-time metal prices, patented processes for extracting antimony by means of a cheap solvent and depositing the pure metal electrolytically. That antimony could be electrolysed from alkali antimony polysulphides was reported by Lukon<sup>1</sup> in 1880, Classen<sup>2</sup>, and Ludwig<sup>3</sup>. Dr. W. Borchers<sup>4</sup> developed a commercial process at one time used in Germany for extracting with boiling sodium sulphide, which solution was conducted through a series of ten cells, wherein the antimony was all deposited. It was found that the metal was deposited in equal quantity, both from thio-antimonates and thio-antimonites; an excess of sodium sulphide, as was proposed by Classen and Ludwig, or sodium hydroxide was found essential in order to prevent separation of sulphur at the anode, the amount of this addition being such that after the removal of the antimony there is at least one atom of sodium to every atom of sulphur—in other words, the reaction takes place best when three molecules of sodium sulphide (Na<sub>2</sub>S) are present for each molecule of antimony sulphide (Sb<sub>2</sub>S<sub>3</sub>). Solution such as sodium hydroxide, potassium hydroxide, ammonium sulphide etc. are very satisfactory for laboratory work but not the most

economical for commercial purposes. Siemens & Halske (D. R. Pat. 67,973, 1892) and von Engelhardt and Nettel (U. S. Pat. 568,843, 1896) used the alkali earth sulphides and regenerated the solution, thus obtaining a cycle with but small losses. A current density of 0.8 amperes per sq. cm. with a voltage of 0.8 gave 76 per cent efficiency, 0.621 kilograms of antimony being refined per kw.-hr.

### LABORATORY WORK

In preparing extraction solutions for test purposes in the laboratory, 27.8 grams of quick-lime and 22.2 grams of flowers of sulphur are mixed in a liter beaker, then covered with 750 cc. of water and the mixture heated on a hot-plate for 45 minutes, stirring continuously to prevent the beaker from cracking. After the cherry-red color has appeared and no more sulphur flowers gather on the surface of the solution it is filtered, cooled, and the filtrate transferred into a bottle and diluted with water to 2 liters. The reaction is as follows:

In testing some antimonial extracts, several 40 cc. portions were taken, giving on analysis 0.962 grams of antimony, to which were added 15 cc. of calcium sulphide solution (sp. gr. 1.18), gram of sodium chloride, 4 cc. of sodium hydroxide solution (10 per cent) and diluted to 400 cc. with hot water. In commercial work, the diluting liquor would be the wash water used in removing the calcium thio-antimony salts from the extraction tanks. In electrolysis, the cathode used was a plane cylinder of platinum foil, 3 by 8 cm., having an exposed surface of 39.3 sq. cm. and weighing 10.71 grams. A heavy platinum wire about 3½ cm. long was attached to the external circuit. A helix of platinum wire ½ cm. in diameter served as the anode, which was placed within the cathode. With a voltage of 1 to 1.2, and a current of 0.4 amperes, 90 per cent of the antimony was deposited in one hour. As the form of the deposit is not a criterion, greater current density could be used to speed up the process. If too large an excess of sodium hydroxide be present, the antimony will form a black, powdery, non-coherent deposit.

A fair estimate of the cost of refining by this process on an industrial scale based on comparative data from general electro-metallurgical costs would be five cents per pound. As a 36 per cent ore sells at about 88 cents per unit, the antimony would cost 4.4 cents per pound in the ore state. After transportation, brokerage and incidental charges are paid, a profit of 2½ to 3½ cents per pound of refined metal would remain at the present price of 13 cents.

## The American Pyrophoric-Alloy Industry\*

### Development of the Rare-Earth Industry in Connection with Welsbach Gas Mantles—the Cerium Group By-Products and Their Domestic Production

By ALCAN HIRSCH

THE pyrophoric-alloy industry is very young, and intimately associated with the rare-earth industry which is also of comparatively recent origin. In order to make the situation clear, it will be necessary briefly to outline the meaning, foundation and history of the rare-earth industry. The term refers to those industries which mine, separate, purify and use the earthy metals or salts of metals formerly considered rare; i.e., gerium, lanthanum, didymium, yttrium, zirconium and thorium. The rare-earth industry was founded in 1885 by an Austrian, Baron Auer von Welsbach, who while investigating certain ores discovered the brilliant light-emitting qualities of their oxides, and invented the incandescent gas mantle. This mantle was made of oxides of lanthanum and zirconium to which a little cerium oxide was added. Welsbach secured patents in various countries, and sold them to investors. About 1887 the industry took root in the United States with the formation of the Welsbach Light Company.

The early gas mantles proved somewhat of a disappointment. Welsbach was in danger of being discredited and pushed his research further, particularly investigating ores of thorium. The early mantles only gave about ten candlepower with a combustion rate per hour of one cubic foot of gas, but the use of thorium salts considerably improved this, and purer and still purer thorium salts were tried until finally they were refined to the extent that they emitted no light at all. To make a long story short, it was found that while thoria should be almost the entire constituent of a mantle, the presence of one or two per cent of other oxides, chiefly that of cerium, was essential to high light-emissive value. This leads us to the present incandescent gas mantle, with which we are indirectly concerned in so far as its production leads to by-products from which pyrophoric alloy is produced.

#### CERIUM RECOVERED FROM GAS-MANTLE WASTES

The original sources of thoria (thorite) in Norway proved totally insufficient in quantity to supply the demand for gas mantles. The manufacturers, therefore, turned to monazite sand, found rather plentifully in Brazil and India and to some extent in North Carolina, as a source of thoria. About 15 to 30 per cent of monazite sand is phosphoric acid, the bases of which mainly consist of various oxides of the rare earths, 20 to 30 per cent oxide, 20 to 30 per cent oxides of lanthanum and didymium in varying proportions, and small percentages of the yttrium and zirconium oxides. All of these are practically useless in any quantity in the gas-mantle business. It is the 2 to 10 per cent of thorium oxide, averaging about 6 per cent, for which

the monazite sand is refined. More than a quarter of a million pounds a year of thorium oxide is produced in the United States from about five million pounds of monazite sand, of which the by-product is mostly wasted. This by-product of so-called "cerium oxides" or "mixed rare-earth metal oxides" amounts to considerably more than a million pounds per annum, and constitutes the raw material for making pyrophoric alloy.

It should here be made clear that what is called "metallic cerium" and used as such, is really a mixture of cerium, lanthanum, didymium, samarium, etc., all very closely allied and very similar metals. It is not necessary to separate them, but the salts for making the metal must be purified. The process for making metallic cerium and the like is described in U. S. Patent 1,273,223, July 23, 1918, to Messrs. Alcan and Marx Hirsch.

The cerium metals are reduced in an electric furnace by electrolyzing their molten salts. The first step is to obtain the electrolyte. We have found that to secure an electrolyte suitable for the continuous commercial production of metallic cerium, certain special precautions are necessary. Certain rather limited ranges of temperature are required for efficiently performing the two processes carried out in the electrolytic cell, and these are called respectively "separating temperature" and "agglomerating temperature." The electrolyte is prepared preferably by using the oxides described above which are the by-product from the incandescent gas-mantle industry. The cerium group oxides are dissolved in commercial hydrochloric acid, reasonably free from sulphuric acid and sulphates, using as little heat as possible, and preferably maintaining an excess of the oxides. The solution consists of a mixture of the chlorides of cerium, lanthanum, didymium, samarium, yttrium, thorium and other rare-earth metals, of which cerium is the chief constituent.

Contrary to common belief, the purity of this solution is not important except for the percentages of sulphur and phosphorus compounds on the one hand, and for the bivalent bases such as iron and aluminium compounds on the other, which should each be reduced below 3 per cent. An excess of cerium oxide will precipitate the iron and aluminium, and calcium chloride (or better barium chloride) will throw down the sulphates and phosphates.

#### PREPARATION OF THE CERIUM SALTS FOR ELECTROLYSIS

The solution is then clarified by filtering hot or settling, and evaporated to dryness. The preparation of electrolyte should be so carried out as to secure the proper surface tension conditions between the fused electrolyte and the fused metal when produced in the electrolytic bath. An excess of certain impurities, in-

\*A paper read at the Fourth National Exposition of Chemical Industries, New York, Sept. 27, 1918.

cluding oxychlorides, such as cerium oxychloride, I believe, tends to reduce the surface tension between the metal and electrolyte in the bath and to alter the viscosity, producing an emulsion of colloidal solution of metal in the electrolyte and preventing the separation of the metal from the bath. The oxychlorides may be removed in either of two ways. The chloride solution obtained as above may be evaporated to dryness and then fused in an atmosphere of hydrochloric acid gas to produce complete reduction as well as to prevent oxidation of the electrolyte by the air or dissociated steam. The wet acid gases are condensed hot and dried, and the concentrated hydrochloric acid gas may be used over again. The second and usual method of making the double chloride of sodium and cerium does not yield a desirable bath for electrolysis. If, however, about 15 per cent sodium or potassium chloride (insufficient to make the double salt), and 15 per cent of ammonium chloride by weight, based on the dry weight of the dissolved rare-earth chlorides, are both added before the evaporation to the chlorides after the excess of iron, aluminium, sulphur and phosphorus impurities are removed; the solution may then be evaporated to dryness and dehydration carried through to fusion of the chloride without the production of characteristics resulting in objectionable tension phenomena in the electrolytic bath. The ammonium chloride is dissociated upon fusion and forms a chlorinating agent as does the hydrochloric acid gas in the first method, and may be similarly recovered and used continuously in the process. When the electrolyte formed in this way is subjected to electrolysis, the alkali chloride accumulates in the cell. After the removal of the metallic cerium or "mischmetall," it may be thrown away or dissolved in hydrochloric acid, purified as above explained, and added to the fresh electrolyte.

#### THE ELECTROLYSIS OF THE CERIUM METALS

The electrolysis is preferably carried out in pots of cast iron high in carbon and silicon, about 8 in. in diameter and 12 in. to 18 in. in depth, usually set in brick work and externally heated. Heat should be applied almost wholly at the bottom of the pot. It is undesirable to fill the cell as described in the literature. We begin the electrolysis with almost an empty cell, heating a small amount of electrolyte with gas nearly to fusion when the electric current completes the fusion. Thereafter continuing the electrolysis, we gradually add electrolyte, building up the charge in the pot continuously until it is practically full, and a termination of the run is brought about. Either carbon or graphite anodes may be used. But they each have a critical density; that is, one above which current may pass without deposition of metal. For graphite this is about six to seven amperes per square inch of anode surface, and for carbon about five and one-half amperes. Furthermore, we find it desirable to maintain a relation between current density at the anode and cathode, the latter being about one-quarter to one-third of the former, in order to secure a desirable electrical circulating heating effect. By adding solid lumps of electrolyte to the bath, the temperature of the cell is lowered when it becomes too hot. It also contributes a portion at least of the charge required for building up the bath.

As the run approaches 24 to 26 hours in duration, when electrolyte made with the alkali salts is used, the sodium salt accumulates in the charge to such an extent that it becomes advisable to terminate the run. We have found that certain precautions for this termination are necessary in order to secure good yields of cerium. Therefore, preparatory to shutting down the run, we turn on the heating torch full blast, and also increase the current, stirring up the charge in the cell thoroughly about every half hour, for two or three hours. The contents of the cell will be in a very fluid condition if the electrolysis has been properly carried out. The current is shut off, the anode taken out, and the bath moderately and thoroughly stirred for about five minutes, care being taken to cease stirring well before the bath begins to thicken. If iron pots are used, it is most practical to break the pot after cooling to separate the button of metal from the electrolyte.

#### PREPARATION OF PYROPHORIC ALLOYS

This relatively pure mixed cerium metal or "mischmetall" is soft and does not spark easily on scratching. Consequently, to make pyrophoric alloy it must be made harder, and is alloyed with about 30 per cent of other metals, chiefly iron, to make the commercial sparking metal or pyrophoric alloy which is formed into small pieces to make the "flints" used in lighters, igniters mechanical fuses, etc. The alloy enters into commerce in the form of small strips, rectangular or round, of varying lengths varying from 200 to 2000 pieces per pound. The most general form is a round piece approximately about  $\frac{1}{8}$  in. in diameter and  $\frac{1}{2}$  in. long, of which there are from 1500 to 2000 pieces to the pound.

The manufacture of these small pieces—the only form in which "mischmetall" is salable—is a most difficult operation requiring what is comparable to equipment for the manufacture of fine jewelry.

#### THE AUSTRIAN PYROPHORIC ALLOY INDUSTRY . .

Baron Auer von Welsbach developed the improvement of hardening the relatively soft cerium with iron to make a hard metal which would emit sparks when scratched. He took out patents on this invention the world over. The German and English patents were litigated and held restricted to the use of iron and its equivalent in substantially the 30 per cent named. This is to say, in England the courts held that Welsbach was entitled to protection only on the iron alloys. The United States courts have sustained the patent much more broadly to include and cerium-containing material hardened with any alloy metal to make the pyrophoric alloy. When Welsbach and his associates developed the pyrophoric-alloy business, they did not form separate companies in each country, but centralized the manufacture of cerium and pyrophoric alloy in the Treibacher Chemische Gesellschaft of Treibach, Austria (a part of the rare-earth cartel or trust). As stated above, they established branches of this Austrian company in England, France, Russia, United States, etc. It was not until some time after the first attack on France by Germany that a pound of cerium was made anywhere in the world outside of the Central Powers so far as I can learn, and then it was made by the New Process Metals Co., which operates under our basic patent on metallic cerium.

Therefore, to reiterate somewhat for the sake of clearness, until the start of the European war the pyrophoric-alloy business of the world was operated as follows: The German and Austrian rare-earth gas-mantle cartel or trust turned over to the Treibacher Chemische Gesellschaft a large part of their cerium residues, which the Treibacher company made into metallic cerium. The Treibacher company exported this metallic cerium to its branches in France, England, United States etc. which branches alloyed the metallic cerium with about 30 per cent of iron and other metals, and cast the alloy into small pieces, selling these pieces to the manufacturers of pocket lighters, miners' lamps, gas lighters, etc. The business of marketing the small pieces of pyrophoric alloy was protected by the patent mentioned which has been contested, and as stated, very broadly sustained in this country.

The American branch of the Treibacher Chemische Gesellschaft was established about 1907, and handled all the pyrophoric-alloy business in this country. After August, 1914, the efficiency of the British Navy made it impossible for the Treibacher company to deliver cerium metal to its agency in the United States. They tried by every means to secure cerium metal from Austria, even trying to import it by the submarine *Deutschland*, but were unsuccessful.

In 1915 the American agency of the Treibacher company got in touch with a chemical company in this country and tried to have this company produce metallic cerium for them. After working several months this company was unable to do so. The president of this company then learned that I had secured my degree from the University of Wisconsin as the result of research on the electrolytic preparation of metallic cerium, and engaged my firm to work out a process for the commercial manufacture of this metal. My brother and other assistants were associated with me in our joint laboratories. After several months of intensive work in the laboratory, metallic cerium was commercially produced of satisfactory quality and in regular quantity. Thereupon the New Process Metals Company was formed which manufactures and sells this material. From that time until April, 1917, the New Process Metals Company furnished metallic cerium to the American branch of the Treibacher Chemische Gesellschaft located in New York City.

#### THE FORMATION OF AN AMERICAN COMPANY

In April, 1917, the manager of the American branch of the Treibacher concern formally notified the New Process Metals Company that he personally, doing business under the name of the American Pyrophor Company, had purchased the business of the Treibacher Chemische Gesellschaft. From April until December, 1917, the New Process Metals Company continued to furnish metallic cerium to the American Pyrophor Company. After war against Austria was declared, the property of the American Pyrophor Company, or the Treibacher Chemische Gesellschaft, whichever you choose to call it, was taken over by the Alien Property Custodian of the United States.

From the foregoing it is seen that the New Process Metals Company developed the cerium business in America. From shortly after the start of the war until the autumn of 1917, it was the only company in the

world outside of the Central Powers making metallic cerium, and the pyrophoric alloy made from this product supplied the needs of the armies and civil populations of Russia, France, England, South America, United States, etc. In this connection, it is interesting to note that the cerium lighters have been extensively used in the trenches, first because of the great scarcity of matches in Europe, and second because of the effect of dampness on matches. We are glad to be able to say that for several years prior to 1918 we supplied the British and French Armies with their requirements of pyrophoric alloy. Now this metal, we understand, is being made in France.

The future of the pyrophoric-metal business in this country is an interesting field for speculation. We hope to be able to maintain it to some degree at least. Frankly, it is our potential ability to market our alloy in the form of lighters upon which we rely for the continuance of our company, and we anticipate that our lighter manufacturing facilities will become so developed and economical as to enable us to meet Austrian competition successfully after the war.

## Speeding Up the Steel Works Laboratory

BY H. C. KIMBER

IN THESE strenuous times it falls to the lot of many to remain at home to produce the materials necessary to the continuance of warfare. It is imperative that every bit of energy and every minute be conserved in order that the army and navy may receive the best material that it is possible to make in minimum time.

The following suggestions and methods of analysis have proved of great value in the production of electric steel. A  $\frac{3}{8}$ -inch flat high-speed drill produces excellent drillings for weighing, as they are practically free from the curls produced by the twist drill. There is a natural tendency for the chemist to spend too much time weighing out the samples. The degree of accuracy necessary may easily be calculated.

For example, it is not necessary to weigh a five-gram sample for sulphur as accurately as a two-tenths gram sample for manganese.

Automatic overflow burettes and pipettes are convenient and almost indispensable in small laboratories having a large amount of work to be done each day. With these burettes and pipettes large quantities of standard solutions may be made up at one time and economically used. A suggestion for the titration bench is shown in Fig. 1. The clips which hold the burette in place are fuse clips used to hold 220-volt fuses. The burette is rigid and every graduation is visible.

An excellent routine method for the determination of carbon in steel is outlined below.

FIG. 1.—BURETTE CLIPS

## THE TRAIN BEFORE THE COMBUSTION

The apparatus, shown in Fig. 2, consists of a calcium chloride tower *B* filled with sticks of sodium hydroxide, or half filled with calcium chloride, and half with soda lime, the former on top; a twelve-inch tube *E* made of  $\frac{3}{8}$ -inch glass tubing, a Y-tube *D*, an equalizer *C*, and a stop-cock *F*. Immediately after the combustion apparatus *G* there is connected to the combination tube an orifice *H* which regulates the flow of oxygen through the train.

The tower *B* containing the sodium hydroxide or soda-lime is connected directly to the oxygen gage *A* and

FIG. 2.—APPARATUS FOR DETERMINATION OF CARBON

Y-tube *D* as shown. The U-tube, which is connected to one leg of the Y-tube, contains enough mercury to fill it four inches deep. The third leg of the Y-tube leads into the equalizer, which must be clean and dry. A delivery tube terminating with a stop-cock *F* of either glass or brass, leads to each combustion furnace and train (only one is shown in the illustration). The equalizer may be a five-gallon bottle or any convenient gas-tight container. If a bottle is used the rubber stopper must be wired in. All connections must be made with high-pressure tubing.

After all the connections are made the stop-cock is shut and the oxygen is let into the apparatus until the difference in the level of the mercury in the U-tube is six inches. This serves as a pressure gage. The cock may then be opened, and the gas allowed to escape until it is reasonably certain that all the air has been replaced by oxygen. The apparatus may then be tested for leaks.

## COMBUSTION APPARATUS

There are a number of good electric furnaces for laboratory use giving a temperature of from 950 to 1100 deg. C. Combustion tubes of quartz or clay are in common use and may be obtained to fit the bore of the furnace.

Boats made of porcelain, quartz, alundum, clay or nickel may be used, but in any case the boat should be lined with a protecting layer of "RR" alundum, alkali free, specially prepared for carbon determination.

A plug of loosely packed asbestos fiber is placed in the outlet end of the combustion tube, together with a catalyzer of either copper oxide, platinized asbestos or platinum gauze. Some authorities maintain that a catalyzer is unnecessary, but its use gives a certain factor of safety. A temperature of about 1000 deg. is the best when no flux is used.

## THE TRAIN AFTER THE COMBUSTION APPARATUS

This consists of an orifice *H*, a delivery tube *J*, a 500-cc. Erlenmeyer flask *L* and a Meyer bulb *K* of special design. The bulb is about 45 deg. from the horizontal. A rack may easily be built for this purpose.

The orifice is made by heating the end of a piece of fairly heavy-walled glass tubing, with constant rolling, until it is nearly sealed. This makes a very small hole which lets the oxygen through at the desired speed. The time between turning on the oxygen and the instant the bubbling begins through the absorption bulb should be about twenty seconds. In other words it should take twenty seconds for the bulb to fill with the barium hydroxide. Following a little practice, the operator should have very little trouble in making these. It is necessary to put a filter of some sort (either a wad of cotton or asbestos) in front of the orifice to catch any ferric oxide which volatilizes while the steel is burning.

The great advantages of this apparatus are that it requires little attention. It is almost impossible for incomplete combustion to ensue due to insufficient supply of oxygen and because of this no difficulty is experienced in burning the sample without a flux at 1000 deg. C. All samples are tested under identical conditions, as the oxygen is always present and at a constant pressure.

## SOLUTIONS REQUIRED

**Barium Hydroxide.**—Dissolve 300 g. of barium hydroxide in 3 liters of hot freshly distilled water. (Put 100 g. in a liter flask or beaker and shake or stir frequently until solution is complete, except for a little precipitate of  $\text{BaCO}_3$  which is sure to form). Make this solution up to 19 liters with freshly distilled water in a 5-gallon bottle. After mixing thoroughly allow this solution to stand for at least 24 hours before using.

**Hydrochloric Acid.**—Dilute 151 cc. of concentrated hydrochloric acid to 19 liters with distilled water.

**Phenolphthalein Indicator.**—Dissolve 2 g. of phenolphthalein in 1000 cc. of alcohol.

## ACCESSORY APPARATUS

It is quite essential to have exactly the same volume of barium hydroxide for each determination. The best means of obtaining this is with an automatic overflow pipette of 80 cc. capacity. A 100-cc. automatic overflow burette may be used for the hydrochloric acid. The phenolphthalein solution is best introduced into the flask containing the barium hydroxide by means of a dropping bottle.

A very convenient way to wash the Meyer bulb is by means of a wash bottle, fitted with a syphon tube and clamp placed on a shelf over the train.

As it is desired to run the oxygen through the train for eight minutes, an eight-minute sand glass or any timing device will prove convenient.

A direct-reading scale is also convenient and may be made by determining the number of cc. for a two per cent carbon steel and measuring this distance on the burette. A draftsman can easily make a scale from these data so that every line will read to a hundredth per cent carbon when the zero or bottom of the scale is at the blank reading. This scale, drawn on a narrow strip of paper and inserted in a glass tube, may be fastened to the burette and adjusted at will by means of rubber bands.

The zero point is placed opposite the blank reading and the percentage carbon may then be read directly from zero up to 2 per cent carbon when a one-grain sample is used.

#### OPERATION OF TRAIN

Draw out 80 cc. of barium hydroxide into a 500-cc. Erlenmeyer flask. Connect this flask to the Meyer bulb immediately. The end of the Meyer bulb tube should reach to the bottom of the solution.

A blank is first run to determine the zero reading. After the flask containing the barium hydroxide is in place the train is connected by placing the stopper in the silica tube. The oxygen is then turned on and allowed to run for eight minutes. At the expiration of this time the oxygen is turned off, the Meyer bulb rinsed out with distilled water from the overhead wash bottle, and the end of the bulb and the sides of the flask washed. Five or six drops of phenolphthalein are added and the solution titrated to a faint pink with the standard hydrochloric acid which has been prepared as described.

If the solutions have been properly made, 80 cc. of barium hydroxide will be equal to about 85 to 86 cc. of the standard hydrochloric acid.

This reading is the zero point for the carbon determination. A standard steel from the U. S. Bureau of Standards, or its standard equivalent, must then be run to determine the factor. The blank reading minus the reading obtained by running the standard steel times 0.06 gives the percentage carbon in the steel if solutions are correct.

#### NOTES

The interval from the time the oxygen is turned on until the instant the bubbling begins through the Meyer bulb is about 25 seconds. This is controlled by the size of the orifice.

The barium hydroxide solution should be prepared as quickly as possible to minimize the precipitation of barium carbonate due to contact with the atmosphere. A guard tube containing soda-lime must be connected to the tube through which the air is admitted into the bottle of barium hydroxide to free the air from  $\text{CO}_2$ .

In titrating the barium hydroxide with the hydrochloric acid the flask containing the solution must be agitated continuously to prevent an excess of hydrochloric acid in one spot. If this is not done the hydrochloric acid will react with the precipitated barium carbonate and the results will be incorrect.

Blanks and standard steels should be run at least once every 24 hours, as solutions change slightly.

The description refers to only one train, but a number of trains may be attached to the equalizer and arranged according to the room available.

#### DETERMINATION OF CHROMIUM IN HIGH-SPEED STEEL

The following method for the determination of chromium in high-speed steel is simple and accurate.

#### SOLUTIONS

*Sulphuric acid*, sp.gr. 1.84, 1:3.

*Microcosmic salt*, 15 per cent solution is distilled water.

*Nitric acid*, sp.gr. 1.42.

*Silver nitrate*. Dissolve 5.28 grams of silver nitrate in 2 liters of distilled water.

*Ammonium persulphate*. Dissolve one pound of ammonium persulphate in 2400 cc. of distilled water.

*Hydrochloric acid*, sp.gr. 1.20, a 5-per cent solution.

*Standard ferrous ammonium sulphate*. Dissolve 57 grams of ferrous ammonium sulphate in 3000 cc. of distilled water and add 100 cc. of sulphuric acid sp.gr. 1.84.

*Standard potassium permanganate*. Dissolve 3.66 grams of potassium permanganate in 2 liter of distilled water.

#### METHOD

Dissolve one gram of the sample in 50 cc. of sulphuric acid (1:3) and add 40 cc. of 15 per cent microcosmic salt. When the steel is completely in solution, add 20 cc. of nitric acid, sp.gr. 1.42, and boil until free from brown fumes. To this solution add 50 cc. of the silver nitrate solution and 50 cc. of the ammonium persulphate solution and boil until the small bubbles of oxygen cease to be evolved; then add 15 cc. of 5-per cent hydrochloric acid and boil until the last trace of the permanganate pink is gone and then remove the flask to the cooling bath.

To the cold solution add 25 or 50 cc. of the standard ferrous ammonium sulphate, depending on the chromium content of the steel, and titrate the excess with the standard potassium permanganate to a permanent pink. A blank and a standard steel must first be run. Blank minus the titration multiplied by 0.1 equals the percentage chromium if the solutions are correct; if not, they must either be corrected or the factor established.

#### NOTES

Upon adding the nitric acid the tungsten present is converted to the soluble phosphotungstic acid.

As vanadium reoxidizes rather slowly, it is advisable to wait for at least 30 seconds to be certain that the correct end-point has been reached.

A 25-cc. automatic overflow pipette is best for measuring the standard ferrous ammonium sulphate.

It is advisable to keep the standard ferrous ammonium sulphate solution in the dark under the titration bench, and pump it into the pipette with a rubber bulb. The rubber tubing will also last longer under these conditions. A blank and a standard steel should be run every other day.

John A. Crowley Co., Detroit, Mich.

#### Ferro Alloys in Japan

Before the war all iron alloys, except a certain amount of ferromanganese, were imported from abroad; but lately a great many plants have been established for the preparation of many kinds of iron alloys. Ferro silicon, ferro chrome, ferro tungsten and ferro molybdenum are most important for the preparation of special steels. The following table shows the amount of such alloys formerly imported.

#### IMPORTS OF FERROUS ALLOYS

|                                                       | 1913<br>Tons | 1914<br>Tons | 1915<br>Tons |
|-------------------------------------------------------|--------------|--------------|--------------|
| Ferro silicon and silicospiegeleisen...               | 1,900        | 1,220        | 1,710        |
|                                                       | \$84,800     | \$85,400     | \$123,870    |

# Radioactive Luminous Materials

Sequence of Scientific Development of Research on Radioactivity Phenomena—Recent Technical Uses of Radium Luminous Materials—Adaption to War Needs

BY WALLACE SAVAGE

IN THE middle of the last century physicists were very much interested in the luminous phenomena produced upon the passage of electric sparks through rarefied gases. The gases were ordinarily enclosed in glass tubes into which platinum wire electrodes were fused at proper places. The Geissler tube was one of the simplest, being a straight tube bulbed at the center and cathode end and having a vacuum of a few millimeters of mercury. Upon the application of sufficient electromotive force, the discharge electrode (cathode) became surrounded by a mellow, deep-blue, luminous envelop, called the "glow-light." From the positive electrode (anode), a peach-red tongue of light extended almost through the entire tube. That these flames were negatively and positively electrically charged air particles was established by their being deflected by the respective poles of the magnet and by their mechanical properties—a small experimentally interposed wheel with mica paddles being rotated by the impact of the

of the arrested negatively charged air particles, which set up a high frequency vibration in the glass wall, which in turn effected the light bearing medium.

## DISCOVERY OF RADIOACTIVITY OF URANIUM

While following out Roentgen's X-ray discovery in its connection with the phenomenon of fluorescence and phosphorescence, Henri Becquerel made an as yet un-

FIG. 1 RADIO-PHOTOGRAPH OF FERRO-URANIUM  
Courtesy, Standard Alloys Co.

stream. Upon absolute exhaustion of the tubes, no current was conducted, which verified further the mechanical nature of the phenomena.

In 1895, Roentgen surrounded one of these types of exhausted tubes (Hittorf's) with black light-opaque cardboard, and discovered that a fluorescent substance (barium-platino-cyanide) was made luminescent when current passed through the covered tube. To his astonishment he found that there were being emitted rays similar to light excepting in that only metals and mineral substances prevented their passage. He had discovered the X-ray, which was to become one of the greatest appliances in the practice of surgery. In subsequent investigations, it was established that the X-ray was produced at the glass wall of the tube by the impact

FIG. 2. RADIO-PHOTOGRAPH OF URANIUM STEEL

foreseen and equally important discovery—radioactivity in uranium. His custom was to expose a fluorescent substance to light action, then to register the lag of the glow by its effect on photographic plates protected from ordinary light. Exposed uranium acted on the plates and Becquerel believed he had established a relation between fluorescence and X-rays. Later he exposed a plate to uranium that had not been recently acted on by light. To his surprise, upon developing the plate, he found that he obtained the same effect as with the light activated uranium. Some permanent actinic effect was indicated. Fig. 1 is a photograph of ferro-uranium (U. 35.4 per cent) taken by its own light with 112 hours of exposure. The light portions indicate the richer uranium crystals. In Fig. 2, the effect of dilution can be seen, the sample being uranium steel (U. 7.74 per cent) photographed with the exclusion of all foreign light.

Mme. Curie, wife of the professor of physics of the Sorbonne, Paris, took up the radioactive investigation. In searching for other examples, she found that thorium exhibited similar phenomena, which were proportional to atomic properties. A given weight of uranium metal had the same activity, no matter whether it was combined as a chloride, bromide, sulphate or nitrate, foreign elements exhibiting no influence upon the activity. She then investigated pitchblende, from St. Joachimsthal, which is a natural uranium oxide with many other metals in association. Contrary to her expectations

from prior work, the radioactivity of this Austrian mineral was four times stronger than would be expected from its uranium content. This contradicted her conclusion as to the atomic relations of this phenomena and indicated that there must be some other associated element present that until now had not been identified.

The mineral was dissolved and the different groups of elements successively precipitated, each residue being tested for radioactivity. The lead group showed a noticeable actinic effect, which has been identified and termed radium G, radioactive lead (at. wt. 206).<sup>1</sup> The copper group was found to contain a member which

FIG. 3. QUARTZ EVAPORATING DISH WITH 0.007 OZ. OF RADIUM EXTRACT FROM 65 TONS OF URANIUM ORE

Mme. Curie named polonium. Actinium came down with the iron group. The essential part of the activity however was found in the alkaline earth group. Upon making the usual sulphate of barium separation, the activity was located entirely in this residue, the radioactive substance being apparently occluded by the barium sulphate. The latter was reduced with carbon in a retort, and the sulphide dissolved in muriatic acid. The radioactive element was further segregated by fractional acid crystallization, its bromine and chlorine salts being more insoluble than those of barium. The element, radium, was finally obtained pure enough to be thoroughly studied. Fig. 3 shows a quartz evaporating dish containing 200 milligrams (valued at \$24,000) of radium salts, which not only furnishes light for registering its own photograph but illuminates the label.

#### THE NATURE OF RADIOACTIVITY

Besides affecting the photographic plate through ordinarily opaque substances, radium ionizes gases—charges them with positive and negative electricity. Three physical phenomena have been identified and termed alpha, beta and gamma rays, of which the latter only is an actual ray. The alpha ray is a positively charged helium particle which is emitted meteor-like from the radium with a velocity of 20,000 miles per second. The beta ray consists of negatively charged electrons, having a mass of  $\frac{1}{6400}$  of that of helium and

a velocity approaching that of light—100,000 to 186,000 miles per second. The alpha particle is stopped by impact with an ordinary sheet of writing paper, while the beta particle is only arrested by metals. All evidence indicates that the beta particle is similar in its properties to the electron found in the X-ray tube, the cathode ray.

The gamma rays are not material in character but are vibrations in the ether. They are produced upon the impact of the beta particles on matter by the subsequent induced vibration which is transmitted to the ether. The elimination of the alpha and beta particles resembles an explosion within the radium. It has been determined that in 1700 years, radium will be half consumed in this disintegration phenomenon.

The greatest scientific interest has been aroused by the establishment of the fact that this disintegration radioactive phenomenon is actually a case of the transmutation of chemical elements. Table I gives the uranium to lead series<sup>2</sup> and Table II, the thorium to lead. The changes in atomic weight will be noted to be four, the mass of the helium X-ray atom removed.

TABLE I—THE URANIUM RADIOACTIVE SERIES

| Series                 | Half-Value Period       | Rays                      | Atomic Weight |
|------------------------|-------------------------|---------------------------|---------------|
| Uranium 1              | 5x10 <sup>8</sup> years | $\alpha$                  | 238           |
| Uranium X <sub>1</sub> | 24 6 days               | $\beta$                   | 234           |
| Uranium X <sub>2</sub> | 15 min.                 | $\beta$                   | 234           |
| Uranium 2              | 2x10 <sup>6</sup> years | $\alpha$                  | 234           |
| Ionium                 | 10 <sup>8</sup> years   | $\alpha$                  | 230           |
| Radium                 | 1690 years              | $\alpha$ $\beta$          | 226           |
| Radium emanation       | 3.86 min.               | $\alpha$                  | 222           |

| Thorium D                     | 3 1 min.                   | $\beta$ $\gamma$ | 208           |
| Thorium D <sub>2</sub> (lead) | 10 years                   | $\beta$          | 208           |

#### THE ALPHA PARTICLE LUMINOSITY

If radium salts are mixed with phosphorescent zinc sulphide, a permanently luminous yellow-colored material is obtained, the light of which is proportional to the radium content. It is found that the impinging of the alpha particles, which are individually visible under the microscope, sets up a vibration in the zinc salt which produces a glowing light. To withstand the perpetual bombardment of these 20,000-mile per second particles, especially strong crystals of zinc sulphide must be obtained.

These are manufactured by sublimation from an electric furnace, the zinc sulphide vapors are condensed in cooling chambers in a fine flour, similar to sulphur. The luminous paint usually carries from 10 to 25 mg. of radium element per 100 gms, depending upon whether a legible contrast glow is needed at the transition periods of day and night—however, too high a radium content is not desirable, on account of the inability of the zinc sulphide crystals to permanently withstand very concentrated impact shocks from the  $\alpha$ -ray without deteriorating.

## LUMINOUS VARNISH

Since the war, the Radium Co. of Colorado has established the Cold Light Mfg. Co. at 558 W. 158th St., New York. This latter company has equipped over half a million Marvelite dials on instruments now being used by our military forces. Fig. 4 illustrates an aeroplane altimeter as it appears in the day and night

FIG. 4.—ALTIMETER DIAL, DAY AND NIGHT

when 9000 ft. above sea level. Fig. 5 shows a compass, clock and air speedometer. The extent of the military use of illuminated indicating devices may be surmised when upon examining an aeroplane, nine instruments are found so equipped. The civil engineers have found it an exceptional boon, for the spirit bubbles on their levels and transits and the marks on their tapes are made sufficiently visible for them to attend to their

FIG. 5.—MILITARY COMPASS DIAL, DAY AND NIGHT. BELOW, AFROPLANE CLOCK AND SPEEDOMETER DIALS

surveys at night as well as in the day without raising any objection from the enemy. Gun sights are greatly aided by being touched up and night aiming is thus quickly accomplished, when a sudden flare exposes an enemy target.

On the sea, now that lights have to be extinguished because of the U-boats, the pilot has compass, log and all, self-illuminated. Radioactive celluloid sheets are now being manufactured from which FIRE ESCAPE, EXIT, electric push button indicators etc. are stamped. No

doubt many valuable applications will be found in engineering practice for this material as distinctive as the uses in "Hunotherapy."

## RADIUM SUBSTITUTE

Mesothorium is also being used for luminating zinc sulphide. Its half period as will be seen from comparing Tables I and II is much shorter than that of radium; however, for temporary dials on inexpensive watches, clocks etc. which are not expected to last longer than four or five years, its use is fully satisfactory. Mesothorium can also be used in cancertherapy.

## Enemy Technical Periodicals Available

Following the passage of the Trading-with-the-Enemy Act, the enemy publications committee of the American Library Association was granted a license by the War Trade Board, whereby universities, colleges, and public bodies of approved character might secure enemy publications of importance to research in science and scholarship, provided the Department of State approved the method and the Censorship Board sanctioned the admission of such material. Two hundred and fifty-five magazines have been approved by these bodies, and approved institutions may enter subscriptions for any of them through the secretary of the committee of the American Library Association, M. L. Raney, Johns Hopkins University, Baltimore, Md. The list of periodicals of interest to technical men here given is abstracted from the report of the committee:

## CHEMISTRY

*Annalen der Chemie.*  
*Chemisches Zentralblatt.*

## Metallography and the War

BY ZAY JEFFRIES

CIVILIZATION is a human product. The utilization of the forces and materials of nature by man has brought about our modern industrial civilization. This has made possible the magnitude and intensity of the present war.

Just as metal has been one of the most important materials—historians pronounce it the most important—used by man in the evolution of our industrial civilization, it is also one of the most important materials used in modern warfare.

Metallography is the "science of metals" according to the Century Dictionary. Previously the term was used to apply only to the microscopic examination of metals, but in later years its scope has been extended to include the constitution of alloys, heat treatment, deformation, and the study of the properties of metals. The physicist or other scientist may perfect apparatus to measure hardness, high temperature, coefficient of expansion, electric and heat conductivity, or to study the positions of the atoms in a crystal, but when used to determine properties of metals for the purpose of producing uniform metal product, these become, like the microscope, tools of the metallographist.

### PRODUCTION OF METALS FOR SPECIFIC USES

The object in producing a metal or alloy is to fit it for use; its properties determine the utility. Metals require different properties in accordance with their use. For example, in a thermostat the chief property may be coefficient of expansion; in a thermo-couple, melting point or thermo-electric force; in a watch spring, resiliency; in an electric transmission wire, high electric conductivity; in a cutting tool, hardness; in a cannon, high strength coupled with resistance to shock; in an airplane part, high strength, coupled with low specific gravity; in acid vats, non-corrodibility; in armor plate, resistance to penetration, etc. For any purpose the metal having the desired properties and costing the least, should be used.

In the production of metals for specific uses, metallography plays two rôles:

1. The control of the manufacturing processes to obtain uniform products;
2. The development of new alloys or processes to serve specific purposes.

Metal parts used in machines and devices such as airplanes, automobiles, engines, cannon, shells etc. must be dependable. To be dependable the product must be uniform. It is much better to use a metal with an average tensile strength of 57,000 pounds per square inch with minimum and maximum 50,000 and 60,000 pounds per square inch respectively, than to use one with an average tensile strength of 75,000 pounds per square inch, but with minimum and maximum 40,000 and 110,000 pounds per square inch, respectively. Engineers must design with the minimum and not the average values in mind.

It is probably safe to state that owing to the pressing need for quantity production, the principal value of metallography in the production of war materials is in the control of processes which tend to make the products uniform. Of course uniformly good results are better

than uniformly poor results so it is to be assumed that the former is the goal. In the study and control of factors leading to the production of uniform product, the metallographist has many tools. The function of each tool is to enable one to determine some specific property of the material which will enable him to predetermine, at least to a certain extent, the utility of the metal part. This predetermination depends on the interpretation of laboratory tests in the light of past experience, the record of performance in use serving always as the absolute guide.

### IMPORTANCE AND LIMITATIONS OF THE MICROSCOPE

Of all of the places of apparatus used by the metallographist, the microscope is probably the most useful and at the same time the least satisfactory. It is the most useful because we owe to it our knowledge of the "proximate" composition of alloys and of the crystalline structure of single component metals. It is the least satisfactory because the examinations are largely qualitative rather than quantitative; too much now depends on the personal equation. Fortunately the present tendency is strongly toward quantitative microscopic examinations. Apparatus to determine hardness, critical points, strength, ductility, expansion etc. yield quantitative results in a large measure independent of the operator and to this extent they are satisfactory as well as useful.

The properties of any metal or alloy will depend on the nature and quantity of each constituent present, the properties of each constituent, and the arrangement of the constituents.

If some condition like the temperature or external pressure changes, then the properties of the metal or alloy will change in accordance with the change of properties of each constituent and the changes in quantity and arrangement of the constituents brought about by the changed condition.

The ultimate constituents are of course the electrons and atoms. If a line were drawn the width of 100 atoms, it would just be visible under the highest powered ultra-microscope. The smallest cube visible under the microscope would consist of more than a million atoms. The metallographic constituents capable of study under the microscope, therefore, must be confined to units larger than one million atoms. But owing to the wonderful developments of the modern physicist, the microscopist can think in terms of atoms even if he cannot see them. No doubt many of the unexplained variations in the properties of metals and alloys could be interpreted if we would extend our observations to the atoms rather than to groups of millions of atoms. The arrangement of the atoms involves the question of the arrangement of the constituents. The atoms of a crystal are arranged in a regular manner and of an amorphous substance in a haphazard manner. The difference in arrangement of the same atoms in the crystalline and amorphous states, produces a marked difference in properties. Internal stress in metals also involves a change of position of the atoms inasmuch as every stress is accompanied with a certain deformation or strain.

But in terms of what can be seen under the microscope, we are interested chiefly in those constituents which separate in relatively large masses. In pure

metals, solid solutions, and chemical compounds, so far as can be seen under the microscope, one constituent only is present. In other alloys more than one constituent can be seen. As the constituents vary in quantity the properties of the alloy change. With the same quantities of given constituents, the properties change in a marked degree with change in the arrangement of the constituents. A splendid example of this is found in 0.9 per cent carbon steel. In normal slow cooling there are two constituents, viz., ferrite about 86.5 per cent and cementite about 13.5 per cent. The cementite and ferrite are in the form of plates arranged in alternate layers. The elastic limit of the steel with this arrangement of the constituents may be over 50,000 pounds per square inch. With the same quantity of ferrite and cementite, the cementite can be spheroidized, that is, changed from flat plates to little spherical globules completely surrounded by ferrite, and the elastic limit may thus be reduced to 25,000 pounds per square inch.

The quantity and arrangement of the constituents of a given metal or alloy may be changed by heat treatment or by mechanical working. If the proper quantity of each constituent and the best arrangement for a given purpose are known, the microscope will aid in the production and control of the desired combination. It is necessary that the microscopist be able to identify the various constituents by means of the various etching and polishing treatments.

The use of metallographic apparatus in the development and control of metals for war materials is very extensive. Such companies as The American Steel & Wire Co., The Bethlehem Steel Co., The United Alloy and Steel Corp., The Halcomb Steel Co., The Carnegie Steel Co., The American Brass Co., The New Jersey Zinc Co., The National Lead Co., The Boston & Montana Copper Co., The Aluminum Co. of America, The General Electric Co., The International Nickel Co., and scores of other companies use up-to-date microscopic and other metallographic means of control in the manufacture of their metal products.

#### WAR USES OF METALLOGRAPHY

Most of the steel now being manufactured is used for war purposes. Many users of steel such as the large automobile and airplane manufacturers, railroad companies, manufacturers of tools, guns, shells, armor plate etc. control their products by metallographic methods. The various departments of the Government dealing with the use of metals also use metallography to control the quality.

In making cannon, the thickness of the metal section is such that longitudinal and transverse tensile tests can be made. These tests show general tendencies as regards the directional properties of the steel due to casting and forging. A rifle barrel, on the other hand, is so small that the longitudinal tensile test only can be made. The directional properties of the steel in a rifle barrel, therefore, are best indicated by means of a microscopic examination. Non-metallic impurities such as slag and manganese sulphide can be seen under the microscope, the relative quantities ascertained, and predictions can be made regarding the effect on the physical properties. In this manner the microscope is used in conjunction with tensile and hardness tests to

control the quality of steel used in rifle and machine gun barrels and other small fire arms.

The microscope is also used extensively for controlling the quality of brass and bronze. In brass the alpha and beta constituents can be differentiated, and the grain size ascertained. The grain size of brass is used generally to control the annealing operations. Metallographic control has aided greatly in the production of cartridge cases and other brass munition parts.

The arrangement and quantity of the various constituents in bearing metals as observed under the microscope enable one to predict the bearing properties better than any physical test outside a bearing test itself. While the application of the microscope in the control of bearing metals is not as extensive as it should be, its value has been recognized by several large companies, making bearings for machines to be used for war purposes.

#### NEW AND SPECIAL FIELDS FOR METALLOGRAPHY

Metallographic control methods are now used extensively on castings of iron, brass, bronze and aluminium. The study of the constitution of some of the aluminium alloys has aided greatly in the knowledge of their properties and control. A new feature has been developed within the last few years, viz., the heat treatment of aluminium. Some of its alloys have critical points and can be hardened and strengthened and at the same time be made more ductile by heat-treatment processes. Rolled aluminium alloys are made now having tensile strength of 55,000 pounds per square inch and 20 per cent elongation in 2 inches.

Another field for metallography is the development of new and better products. Just as the metallographist frequently makes important scientific contributions to physics and chemistry, so do workers in all branches of industry and science add to the sum total of metallographic knowledge and hence to the new developments. In fact, some of the new developments come from unexpected quarters. Sometimes the developments are the results of accident, but they are generally the result of scientific elimination. The science of elimination consists largely in the choice of the proper scope of materials and processes to produce a certain product and the elimination of all but the most suitable by planning experiments to study one variable at a time.

In this connection such men as H. M. Howe, Bradley Stoughton, R. R. Abbott and P. D. Merica are working practically their entire time on development problems in the United States. A. Sauveur is doing work in France for the United States Government along metal development lines. Many metallographists of England and France are engaged in the same kind of work for their Governments.

In addition to this many of the large industrial companies are carrying on research work to produce better alloy combinations and better treatments. In particular, great strides have been made in the production and treatment of special steels for aircraft-motor construction and for armor plate. The details of these developments probably will not be made public until the close of the war. Only when the details are made public can the magnitude and importance of this development work be adequately appreciated.

Cleveland, O.

## Chemical Iron Ware

### A Description of the Silicon Irons—Acid-Resisting, a Relative Term—Comparative Action of Corrosives—Acid Resisting Castings

RECENTLY considerable controversy has arisen in England over a paper read by Professor Camille Matignon before the Academic des Sciences of Paris<sup>1</sup> on his investigations of various commercial alloys of ferrosilicon. Starting his investigation in 1913, at the very start of the commercial development of this industry, Dr. Matignon had great difficulty in getting samples, so that his report probably did not represent simultaneous comparisons of the various products.

Considering the rapid developments being made in this field, no report less than present day comparisons is of value. Several concerns are manufacturing this type of chemical ware in America. The compositions of six of the alloys analysed by Dr. Matignon are reported as follows:

|            | Métallure | Elianite I | Elianite II | Ironac | Duriron | Ferroboron |
|------------|-----------|------------|-------------|--------|---------|------------|
| Si.        | 16.92     | 15.07      | 15.13       | 13.16  | 15.51   | 4.9        |
| Fe.        | 81.05     | 82.40      | 80.87       | 83.99  | 82.23   | 69.8       |
| Mn.        | 0.88      | 0.62       | 0.53        | 0.77   | 0.66    | 3.3        |
| Ni.        | .....     | .....      | 2.25        | .....  | .....   | .....      |

| C.         | 0.592     | .....      | 82          | 1.08   | 0.83    | .....      |
| P.         | 0.173     | .....      | 0.06        | 0.78   | 0.57    | .....      |
| S.         | 0.01      | .....      | 0.03        | 0.05   | 0.01    | .....      |
| Ca and Mg. | .....     | .....      | .....       | .....  | .....   | 15.4       |
| B.         | .....     | .....      | .....       | .....  | .....   | .....      |

The following are extracts from *Engineering*, Vol. CVI, pp. 154-156, Aug. 9, 1918, giving a full account of tantiron. While it does not pretend to offer a comparison of the several products, it shows the present state of this industry in England and America.

The manufacturing chemist and metallurgist are greatly restricted by the limitations of applicability of their apparatus. In many processes, the difficulty is not so much to obtain the raw materials as to find furnaces, containers, pipes etc., that will bear the chemical and physical stress of the reactions, and to avoid the contamination of the products by the substances with which the reactions bring them into contact. For these reasons many a promising process never gets beyond the laboratory stage; hence, also, the cry for substitutes of rare, expensive materials, as well as the natural distrust of them. The enhanced activity of certain chemical industries has much increased the demand for refractory materials and acid-resisting alloys. Experiments with acid-resisting iron alloys are not new, of course. Wollaston made a silicon-iron, and he may not have been the first. Engineers and electricians found silicon-iron very useful for special purposes, and many attempts were made to construct chemical plant of silicon-iron and other iron alloys. Tungsten, chromium and nickel were tried. But foundrymen seemed to be unable to make vessels even of moderate dimensions of such materials, and it was not till 1912 that an acid-resisting iron alloy of sufficient uniformity and strength for the engineer to deal with was put on the market.

It was the tantiron of Mr. R. N. Lennox, made by the Lennox Foundry Co. of Glenville Grove, New Cross, S. E. Since then silicon-iron and other non-corrosive iron alloys have been brought out by several firms. Both the "duriron" of the Duriron Castings Co. of Dayton, Ohio, and the "ironac" of the Houghton Co. of London, are silicon-irons, like the métallures of A. Jouve, one of the first in this field, and the Italian elianites, which contain about 2 per cent of nickel. The American rights for tantiron were taken over in 1913 by the Bethlehem Foundry and Machine Co., Pennsylvania. "Ferrochrome" is supplied by the Electrometallurgical Co. of Niagara Falls; the "feralun" is likewise an American product, and German activity in the field will not have ceased during the war; in addition to "neutraleisen," there are ferro-chromes and ferro-borons.

#### ACID-RESISTING IS A RELATIVE TERM

Tantiron is a silicon-iron, containing about 15 per cent of silicon. In appearance it is a silvery-white close-grained cast-iron, and has the general properties of a machinable cast-iron. One special brand of tantiron is very hard, and not machinable; another quality resists hydrochloric acid which the others do not. It melts at about 1200 deg. C., can be cast, ground with carborundum, cut with the saw, drilled, screw-cut and tapped etc. Sofar as chemical and mechanical corrosion is concerned, it is a superior iron and is used for cast vessels or in the shape of linings for those of steel or iron. It does not rust, except at the skin, and the rust is removed by pickling in diluted sulphuric acid or by grinding. The tantiron itself is not—or practically not—attacked by sulphuric, nitric, or acetic acid, concentrated or diluted, boiling or cold, and indeed not by most chemicals. One kind already mentioned—a more recent invention—also resists hydrochloric acid equally well. Carbonic acid attacks it slightly, but the corrosion is only about one-thousandth that of cast-iron. Alkalis corrode it about as much as they do cast-iron; chlorates and perchlorates do not corrode it, and it will resist chlorine gas up to a temperature of 105 deg. C. But sulphur dioxide corrodes tantiron badly. In view of this latter fact, the suitability of tantiron pans and basins for the concentration of sulphuric acid is rather surprising. Large pans have been in use, however, we are informed, since 1912, and some 25,000 basins are actually in use in sulphuric-acid works. There is some slight corrosion, of course, and there are breakages, partly due to the material, partly to improper treatment by unskilled labor, which causes many small and large accidents in these days of rapid plant erection and high-pressure activity. The maintenance cost of pans and basins is about 2½d. or 3d. per ton of acid concentrated. After boiling 100 grams of the alloy for

<sup>1</sup>Comptes-Rendus de l'Académie des Sciences, Vol. 166, pp. 815-818, May 21, 1918

17 hours, 10 per cent sulphuric acid was found to have dissolved 0.13 gram of tantiron, 25 per cent nitric acid 0.25 gram, and 30 per cent hydrochloric acid 0.16 gram.

The term "non-corrodible and acid-resisting iron" is misleading, as all such general terms are. Every chemist knows that he must not allow metals to glow in his platinum crucible, as they would form fusible platinum alloys, and that caustic alkalis and certain alkali salts, and even the sooty flame of the gas burner, will ruin his crucible. Tantiron also has its peculiar weaknesses. It resists hot sulphuric acid much better than cold acid, and many instances of attack are so far inexplicable. In one case, a tantiron tower containing vapors from boiling sulphuric acid showed defects in the top sections, without any attacks on the bottom sections. The top sections were replaced several times; the bottom sections, which had been in use for eighteen months, were taken out and inserted in the top, when they were attacked within a fortnight; yet temperature determinations at different points of the tower never showed differences exceeding 5 deg. C. In other cases, supply missing part sulphuric acid, are being carefully freed from arsenic by sulphuretted hydrogen, attacked the tantiron nearly three times as quickly as the original acid. But the amount of attack is, of course, exceedingly small. A tantiron vessel weighing 4950 grams had 600 tons of sulphuric acid passed through it during concentration with a total loss of weight of 12 grams. The attack is namely on the surface or skin, which should, therefore, be removed when corrosion tests are conducted.

#### CHEMICAL COMPOSITION AND PHYSICAL PROPERTIES OF TANTIRON

Though the iron carbide seems chiefly to be attacked, the corrosion is apparently uniform; under the microscope, acid-corroded tantiron keeps its smooth surface, while cast-iron shows irregular corrosion. Mr. Lennox prefers to have no carbon in the iron at all. His raw materials are cast-iron, scrap, and old tantiron, and further ferro-silicon. The latter is obtained with about 12 per cent silicon from Middlesborough, and in a 50 per cent grade from Norway. The average composition of tantiron is in per cent: Silicon, 14 or 15; total carbon, from 0.2 to 0.6; manganese, 0.25 to 0.35; phosphorus, 0.16 to 0.20; sulphur, under 0.05. The three kinds mentioned, machinable tantiron, hard tantiron and tantiron for hydrochloric acid, differ little in composition, but the small fractions of additional constituents are very important. To study their influence, ingots are poured from furnace charges of 1 ton, to which additions are made in very small increments; the ingots are then tested chemically and mechanically. The sulphur and manganese, in their percentage, seem to be of no consequence. The phosphorus is deleterious, mainly probably because it is not uniformly distributed, but concentrated in spots. As phosphorus is added to iron, the freezing point is first lowered, and then, when 10 per cent of phosphorus is exceeded, rises again, but the cooling curves are not regular, while the freezing point curves of silicon-iron and chrome-iron show a very slow but steady rise with increasing percentages of those elements. (See Fig. 1.) Impact tests are made

on  $\frac{3}{8}$ -in. square bars, which are not notched; they break, e.g., under stresses of from 8 ft.-lb. to 10 ft.-lb., against 12 ft.-lb. to 14 ft.-lb. in the case of cast iron. On the whole, the strength of tantiron is about 25 per cent less than that of cast iron. The following is a summary of the comparative properties of tantiron and cast iron (the latter figures in brackets): Density, 6.8 to 7.0 (7.3); tensile strength, 6 to 7 (9 to 10) tons per sq. in.; transverse strength, bars of 12 in. by 1 in., 1600 lb. (2500 lb.); crushing strength per inch tube, 34 (40) tons; melting point, 1200 (1500) deg. C.; hardness, 1.6 (1); heat conductivity, 8 (10); electrical resistance, 10 (8); resistance to corrosion, 1000 (1); contraction allowance in casting,  $\frac{3}{16}$  ( $\frac{1}{8}$ ) in. per ft. As regards

other properties, also of other materials, the comparative order for iron, tantiron, lead, quartz, and stone-ware is: Transmission of heat, 230, 215, 115, 28, 20; hardness, 24, 35, 1, 52, 32; density, 7.3, 7, 11.3, 2.6, 2.0; melting point, 1150, 1200, 335, 1900, 1800 deg. C.

#### COMPARATIVE ACTION OF CORROSIVES

With respect to corrosion by chemicals, there is generally a first attack, followed by relative immunity under continued exposure. The following figures indicate the percentage losses of tantiron after boiling for 24, 48, 72 hours; the greater action during the first 24 hours is largely due to the already-mentioned skin effect, the outer surface having been changed by contact with the sand in which the tantiron is cast; this skin is removed in the foundry, as we stated.

|                              | First<br>24 Hours | Second<br>24 Hours | Third<br>24 Hours |
|------------------------------|-------------------|--------------------|-------------------|
| Sulphuric acid, 98 per cent  | 0.10              | 0.02               | 0.02              |
| Sulphuric acid, 30 per cent  | 0.07              | 0.00               | 0.00              |

| Chromic acid, 10 per cent    | 0.07              | 0.00               | 0.00              |
| Tartaric acid, 25 per cent   | 0.05              | 0.03               | 0.03              |
| Iodine (sat. sol.)           | 0.00              | 0.00               | 0.00              |
| Bromine water (sat.)         | 0.01              | 0.01               | 0.00              |
| Bleaching powder (sat. sol.) | 0.04              | 0.01               | 0.01              |
| Copper sulphate (acid sol.)  | 0.00              | 0.00               | 0.00              |
| Copper sulphate (alkaline)   | 0.00              | 0.00               | 0.00              |
| Ferric sulphate (acid sol.)  | 0.06              | 0.00               | 0.00              |
| Zinc chloride, 30 per cent   | 0.03              | 0.00               | 0.00              |
| Ammonium chloride sol.       | 0.05              | 0.02               | 0.01              |
| Fused sulphur                | 0.06              | 0.01               | 0.00              |
| Fused nitrate of ammonia     | 0.00              | ...                | 0.00              |

To meet the peculiarities of the material, it is desirable that designers of parts to be made in tantiron should bear the following rules in mind: large flat surfaces should be avoided; corners be rounded; slots be used by preference to bolt holes; facing strips be narrow and of ample height; the effects of expansion and contraction should be well-considered: coreing and

moulding be made easy, by preference without the use of chaplets to support cores. Among the chief products now made wholly or partly of tantiron are acid pans, basins, stills, bleachers, denitrating towers, autoclaves, condensers, pumps, stop cocks, valves, pipes and fittings, electrodes etc. Frequently a tantiron lining will suffice to prevent either chemical or mechanical erosion. The largest tantiron casting so far constructed weighed 7½ tons.

The greatest care is bestowed upon clean moulding, which is mostly done by women, and use is made of rotating strickles in preparing the moulds for parts of circular section. For lining pipes with a tantiron, the pipe must be suspended vertically by a flange with the core in proper position, the pipe to be lined being weighted below; if the liquid tantiron were poured into a horizontal pipe, the pipe would curve. This practice is generally adopted for lining iron or steel, wherever possible, and the part to be lined is well dried, but not pre-heated. The adhesion between the iron and the tantiron is said to be good fusion taking place between the surfaces; the adhesion is tested with the acid of paraffin oil. The lining may have a thickness from ¼ in. up to 1½ in. and more. The subsequent finishing of the product is largely done with the aid of carborundum wheels and grinders. It is rather curious that the fine tantiron particles torn off by the tools do not spark; there is only a glow. Drills, saws and planers are also used.

#### ACID RESISTING CASTINGS

The basins for the heating and concentration of sulphuric are mostly of the plain porcelain dish style, but are provided both with a lip and an arc-shaped baffle (not shown); they are supplied also in the Webb and

FIG. 2.—CASCADE ACID CONCENTRATING BASINS

Dyson styles (Fig. 2). The basins are arranged in cascade, so that the hot acid drips from the lips of one basin into the one next below, and the baffle prevents the acid from streaming right over the basins to the lip. Provisions for more efficient circulation and stirring of the acid in the basin is made in the "Mackenzie field tube evaporator basins," also supplied by Mr. Lennox; this style has calix shape, being a tube opening out into a basin; a "field" tube fits concentrically into the cylindrical portion and promotes active circulation. Other basins are provided with covers and necks, and made corrugated, and they serve generally also for the concentration of corrosive liquids, such as zinc chloride, lead nitrate, etc.

The concentration of nitric acid requires more varied apparatus, which have successfully been made of stoneware in the past few decades. When the war broke out, the stoneware works of this country were not able to deal with the demands, and tantiron vessels, which

can be made in a few days, while good stoneware requires months, were largely adopted. Valentiner plants comprising a still, condenser and coils, built up of pipes and return bends flanged together, all of tantiron, are now made. The denitrating tower illustrated in Fig. 3 is an interesting novelty. The spent acid of nitroglycerin works consists of diluted sulphuric acid, which has to be concentrated again, and some nitric acid, which is to be regained by distillation. There may also be small globules of oily nitroglycerin which might coalesce if the evaporation were carried on in pans. The tower, 15 ft. high, is built up of socket pipes, 14 in. in diameter, and is packed with quartz fragments; the acid enters at the top and steam at the bottom, and the nitric acid and vapor condense in the cylinder by the side of the tower. Nitric-acid stills are also used for the distillation of acetic acid. The autoclaves for making ammonium nitrate from cyanamide at a temperature of 120 deg. C. and a pressure of about 2 atmospheres resemble one style of nitric acid retorts. The outer vessel is a jacket of cast iron, the inner vessel of tantiron forms the saturator; the height is 8½ ft., and the diameter 4½ feet.

FIG. 3.—DENITRATING TOWER

Acid eggs, apparatus for forcing up corrosive liquids with the aid of compressed air, are made of two tantiron cups, joined by their top flanges so as to form a horizontal cylinder with spherical ends and one common flange on the vertical middle plane; they are provided with acid inlet and outlet valves and an air pipe, and are supplied in large sizes. The pumps of the works, reciprocating and centrifugal, do not differ much in appearance from ordinary pumps; the barrels and impellers and pipes are made of tantiron or lined with it. As these parts of hard tantiron cannot be machined or repaired, it is recommended to keep spare parts ready for cases of accident. Centrifugal pumps are supplied for lifting 6000 gals. of acid or corrosive water, etc., per hour, against a head of 50 ft., running at 1600 r.p.m. Slime pumps for conveying the crushed quartz in gold mines are likewise made of tantiron, to obviate the heavy erosion of the pipes by the gritty quartz particles. For the same reason, tantiron-lined steel pipes are used in the Rand mines, South Africa, for the sand-filling plant. When the pillars left in the galleries below are to be removed, the galleries have to be refilled with the finely crushed quartz from the vast white waste mounds which form a conspicuous feature of the district. The spoil is flushed down the pipes with water. The first pipes used, steel pipes, were ruined

by 6000 tons of sand; porcelain-lined pipes were then tried, which could stand up to 50,000 tons; the tantiron pipes, introduced four years ago, are still doing duty, and their life capacity is estimated at 500,000 tons. Similarly-lined steel pipes and tantiron pipes, up to 2 ft. in diameter, are in use for ash ejectors, especially on board ship where heavy erosion and corrosion by the caustic ashes and the sea water have to be guarded against.

In stop cocks and valves of tantiron, corrosion by acid sodium bisulphate (the acid cake residue of the distillation of nitric acid from salt and sulphuric acid) erosion by grit, rusting and sticking are the chief sources of trouble to be met. Here, again, tantiron completes with lead and stoneware, and its advantages lie in greater strength and indifference to high temperatures and frost. A great variety of cocks, valves, T-pieces, straight and bent socketed pipes, provided with threads, are made in tantiron.

Of other specialties, we mention the corrosive-vapor drying and baking ovens, the flat doors and walls of which are lined with sheets of tantiron, which are screwed on. Tantiron can be rolled at about 700 deg. C., but is brittle then. Another specialty is the tantiron electrode for cyanide baths (silver and gold), and also copper baths etc., replacing iron and other alloy electrodes, which are not insoluble, and very objectionable on this account, or more expensive than tantiron. For the same reason, steel-mixing mills for the manufacture of manganates, the balls and stirrers of other mills, and many apparatus used in the acid and dye and other chemical industries, are made of tantiron.

Like every manufactured article, tantiron is constantly being improved, and does not claim to have reached final perfection. Acid-resisting materials must possess various properties which are not easily combined, and possibly not capable of combination. A compromise has to be accepted.

## Ulco Hard Metal

By FRANCIS C. FRARY AND STERLING N. TEMPLE

THE development of this new hard-lead alloy may be considered as a by-product of the war and also of the Atlantic City meeting of the American Electrochemical Society. At the time of this meeting, in the spring of 1915, the heavy demand had raised the price of antimony to some seven times its normal value, and the larger consumers were naturally looking for substitutes. Mr. H. B. Coho, formerly chairman of the New York Section of the American Electrochemical Society, in talking with one of the authors at that meeting, mentioned the need of a substitute for antimony in hard lead, suggesting cerium, and explaining the interest which the United Lead Co., with which he was connected, had in such an alloy.

It so happened that in the work done by Frary and Badger<sup>1</sup> on the production of metallic calcium, one lot of lead-calcium alloy had been made, and the fact noted that it was harder than lead. Calcium being easier to produce than cerium, it was considered a better starting point for experimental work. But when the calcium-

lead alloys were studied we found that a considerable amount of calcium must be used in order to get a hardness approaching that of antimonial lead (17 Brinell), and that this alloy did not stand remelting but easily lost its calcium. Upon making up similar alloys of lead with other metals of the alkaline earths, it was found that each hardened lead to a different but marked degree. Further experimentation brought to light the surprising fact that if two or more of the metals were used together, the hardening effect was several times that which would have been found if only one were present in the same total quantity, thus making it possible to produce an alloy which was harder than antimonial lead, but contained so little alkaline earth metal that it could be remelted several times without losing appreciably in hardness, and actually contained well over 99 per cent lead.

### METAL IS HARD AND CASTS FREE FROM BLOW HOLES

The rights to this alloy (U. S. Patents 1,158,671 to 1,158,675 inclusive, and corresponding foreign patents) were acquired by the United Lead Co., who proceeded to install a plant at Keokuk for its manufacture. The surprising toughness of the metal, the possibility of making it much harder than any other commercial lead alloy (some samples have been made which were as hard as steel) and the fact that it made castings entirely free from any trace of blow-holes and expanded to fill a void, like type-metal, made both the inventors and the company feel that it would have a useful function to perform, even though, in the mean time, the price of antimony had dropped to a point where the new alloy could scarcely compete for ordinary uses.

### TEST BY BUREAU OF STANDARDS

These hopes have been fulfilled and the alloy has taken its place among the important bearing metals, its high melting point, excellent structure and low coefficient of friction giving it a unique importance. The following report of tests from the U. S. Bureau of Standards confirms in an official way the experience of a number of firms who have experimented with it:

A 10-lb. ingot of the Ulco Hard Metal, the original Brinell hardness numeral of which was 25.2 at a load of 500 kg., was melted down, and chilled castings were poured at various temperatures with the following results:

| Temp.,<br>Deg. F. | Temp.,<br>Deg. C. | Brinell<br>Hardness<br>Numeral |
|-------------------|-------------------|--------------------------------|
| 650               | 343               | 23.5                           |
| 700               | 371               | 25.1                           |
| 750               | 399               | 25.0                           |
| 800               | 427               | 25.7                           |
| 900               | 482               | 27.8                           |
| 1,000             | 538               | 22.0                           |

The metal was fluid at 650 deg. F., and though the maximum hardness was produced by pouring at a temperature of about 800 deg. F., the hardness was not greatly reduced by pouring at higher temperatures.

Test bearings were then poured and service tests made in an Olsen testing machine, tests on genuine babbit being made at the same time to serve as a basis for comparison. The table below gives the results of these service tests:

| GENUINE BABBIT |                                |                            |                   |                          |                  |                 | Friction<br>in<br>Weight<br>Grams |

| 900   | 408 | 22,300 | 59 | 138 | 22 | 40 | 24 | 0.015     |
| 1,000 | 405 | 23,200 | 66 | 151 | 36 | 65 | 22 | 0.014 (a) |

(a) Bearing still in good condition.

The Ulco Hard Metal bearing was still running excellently at 100 lb. per sq.in. load, but as the capacity of the testing machine was reached the bearing could not run to failure, as in the case of the genuine babbitt bearing.

It will be noticed that the Ulco Hard Metal ran considerably cooler than the genuine babbitt, the friction was less and the wear also a smaller amount. It should be borne in mind that the specific gravity of the Ulco Hard Metal is much greater than that of genuine babbitt, and for equal loss in weight the volume loss would be less in the case of Ulco Hard Metal.

These tests were repeated on new samples with substantially the same results as above. A test was also made in which no lubricant of any kind was used in the bearing. The bearing was run at a speed of 700 r.p.m. and 50 lb. per sq.in. pressure, and after about 10 min. the metal began to flow and adhere to the steel shaft, scraping out more of the metal from the bearing. The shaft was not injured in the least by the test, and the metal that had adhered to it could be readily removed with a knife.

Tensile tests on Ulco Hard Metal and genuine babbitt cast under similar conditions gave the following results:

|                 | Tensile Strength, Lb. Sq.In. | Elongation, Per Cent in 1 In. | Reduction of Area, Per Cent |
|-----------------|------------------------------|-------------------------------|-----------------------------|
| Genuine Babbitt | 10,600                       | 15                            | 8                           |
| Ulco Hard Metal | 13,000                       | 5                             | 1                           |

The fracture of the babbitt showed blow-holes, reducing section approximately one-fourth, though the Ulco specimens were sound throughout. The average elastic limit in compression of Ulco hard metal was found to be 11,525 lb. per sq.in.

## ALLOY RESEMBLES LEAD IN MANY RESPECTS

The alloy has the general appearance of lead, may be cast, drawn, rolled or extruded; its specific gravity and melting point are practically identical with those of lead, and its composition so nearly the same that two analysts reported it as (1) commercially pure lead, (2) pure lead, heat treated. It may be diluted with ordinary lead to produce alloys which are not so hard, and tin and bismuth may be added if desired, but if more than a very small amount of antimony be added, the alkaline earth metal separates out and the alloy is ruined. It has the metallic ring of bell metal, and none of the brittleness of antimonial lead.

One of its peculiar properties which will doubtless interest metallographers is its pronounced increase in hardness upon standing or aging, and the possibility of accelerating this process by aging at steam heat. It is a fact not generally known or noticed that antimonial lead increases slightly in hardness for a few hours after casting, but the amount of this change is not large. With the lead-alkaline earth alloys, however, the fact was noticed early in the experimental work that all samples increased markedly in hardness for some time after being cast, so that it was entirely impossible to determine the hardness of the alloy until it had aged several days. Figures obtained in the research laboratories of the United Lead Co. show that an alloy with the Brinell number of 8 increased to 10 on standing a day, another with an initial hardness of between 13 and 16 reached 17.6 after standing two days, 19.6 after

standing eight days, and 20.7 after fifteen days. A part of the same sample, after being aged one day at 100 deg. C. had attained a hardness of 25.4.

## SOLID SOLUTION OF ALKALINE-EARTH METALS IN LEAD

Bars of the metal which have been cast in an iron mold and broken seem to show a slight difference in fracture which would indicate a chill effect at the surface which was in contact with the iron. The main body of the bar will exhibit a fine hackly fracture, like an alloy steel,

FIG. 1.—SECTION FROM A PIECE OF ULCO LEAD SHOWING FRACTURE

but a more distinctly crystalline structure appears for a depth of about  $\frac{1}{16}$  in. from each surface which was in contact with the mold. The effect is absent at the surface which formed the top of the ingot. Such metallographic work as has been done upon the alloy has not, as far as we are aware, developed any definite structure, and everything seems to indicate that we have to deal with a solid solution of the alkaline-earth metals in lead. This is true only for alloys containing small amounts of the alkaline-earth metals such as Ulco Hard Metal; these are stable toward water and have no taste, while alloys with several per cent of the metals break with a coarser structure and have the "electrolytic" taste with which everyone is familiar who has tried to test a dry battery by taste.

The possibility of using this alloy to replace babbitt and thus save tin for war uses is of course very important now, and its superior quality would indicate that such a substitution would not be disadvantageous. It has also found a field in the manufacture of various small castings; bath-room supply and waste pipes, nickel-plated, are at present made from it, and its hardness combined with ease of casting should recommend it for various other small castings, now made of brass.

Tin Mining is very profitable in Bolivia at present prices. The Llallagua Tin Co. made a gross profit of eight and one-half million dollars in 1917, which is about four times that of the year previous. Their production of ore concentrates increased from 7460 long tons in 1916 to 11,250 tons last year. The mine showings are figured at 261,902 tons; averaged at 14.33 per cent, they are estimated to offer 37,500 tons of metallic tin.

## Magnesium

### Some of Its Present Commercial Applications

**M**AGNESIUM, the lightest of commercial metals, was little known and little used in this country before the outbreak of the war in 1914. Prior to that time a small amount of this metal was imported in powder form for flash-lighting, and a few manufacturers used it in stick form with the metals.

The withdrawal of the German product from the market necessitated the development of its manufacture in this country to supply the existing demands. Allied purchases in the United States and our own entrance into the war have stimulated the production to a marked degree, on account of its use for flares and illuminating bombs of all kinds. Government bulletins show an increase in production in the United States, from 75,400 lb. in 1916 to 115,800 lb. in 1917, and to 116,938 lb. in the first six months in 1918.

Magnesium is a common element in many minerals occurring in America so that its production, like that of aluminium, can be increased to meet almost any demand. All that is necessary is to develop our water power, as cheap power is essential to the production of this metal. This possible future development is vital to those who are now using magnesium and to others who are contemplating its use.

We are today only learning how to use metals, and the future of the metal industry, in the application of alloys to various uses, will be like rubbing Aladdin's lamp. The future uses of magnesium may be as large a factor in revolutionizing industry as aluminium has been. Magnesium, however, cannot be said to be a competitor of aluminium; it is a co-worker with that metal. In other words, where it will replace aluminium in one industry, it will create a much greater use for it in others.

Magnesium in aluminium is, then, one of the present commercial uses. The first action of magnesium in aluminium is as a deoxidizing agent. At the temperature of molten aluminium, magnesium will reduce carbon monoxide and carbon dioxide, gases which are readily dissolved in molten aluminium and which cause endless trouble in cooling. As a result of its deoxidizing properties, it makes aluminium castings more dense.

All of the magnesium introduced into aluminium is not consumed in deoxidizing, and the resulting alloy is a much improved metal. As an alloy, magnesium makes aluminium stronger and gives it a finer grain. In addition to this it improves its machining qualities.

While all of these qualities are obtained with  $\frac{1}{2}$  per cent. an increase in the amount of magnesium with an equal percentage of copper gives a very dense metal. For instance, a 3-in. flanged valve with  $\frac{1}{2}$ -in. wall (96 per cent Al, 2 per cent Cu, 2 per cent Mg) was tested to 300 lb. per sq.in. hydraulic pressure without leaking. This valve is now in service under 400 lb. per sq.in. pressure of acetic acid. Other tests have shown equally good results with this alloy.

The commercial advantage of an alloy of this sort is illustrated in a comparison of its price with that of brass or bronze. Considering metal costs only, brass will cost about \$0.26 per lb. and the aluminium alloy

about \$0.43 per lb., but the difference in the specific gravity (the aluminium alloy is about  $\frac{1}{3}$  that of brass) makes the price for any individual piece or casting much less. That is, a brass casting weighing 1 lb. would have a metal cost of \$0.26 per lb. whereas the same casting made of the aluminium-alloy would cost  $1\frac{1}{3}$  of \$0.43 or \$0.14  $\frac{1}{3}$ . The advantages here are evident, especially in view of the fact that aluminium takes a better and a more acid and alkali-resisting polish when it contains a small percentage of magnesium.

The deoxidizing properties of magnesium have been known and applied commercially for ten or fifteen years. Magnesium is used to deoxidize nickel and monel-metal castings; in fact, it is quite essential in this industry.

The same property has recently been applied to the making of copper castings and with some very far reaching possibilities. In deoxidizing copper, magnesium is used in proportions of 0.03 per cent to 0.08 per cent, that is, 1 lb. of magnesium will deoxidize from 1200 to 3000 lb. of copper. As 80 per cent to 90 per cent of the magnesium introduced is consumed in deoxidizing, practically none of it shows in the analysis of the finished casting. Magnesium also gives a very dense metal, so that it is possible to make copper castings having electrical conductivity equal to, if not greater than, that of rolled electrolytic copper. The development of this use in the electrical industry makes possible the substitution of copper castings for machined copper thus saving machining costs, reducing the copper scrap and decreasing production costs. Other applications may follow this important use for magnesium.

The action of magnesium in brasses and bronzes is similar to that in copper and an equal amount of magnesium will deoxidize these alloys. As a deoxidizing agent in these alloys, magnesium is cheaper than phosphorus or phosphor-copper, and may be used in their place, except where specifications require a final analysis showing phosphorus. Its cheapness, combined with the fact that it gives a dense and stronger casting, will greatly increase its use in this branch of the metal industry.

A remarkable result of introducing less than 0.1 per cent of magnesium in brasses is that the tensile strength of a brass will be increased from 40 to 60 per cent. This is not obtained at the expense of elongation or ductility as the elongation is increased at the same time.

Magnesium, contrary to the usual rule, is a good bearing metal. Some of its alloys have wearing qualities equal if not superior to cast iron. Its hardness is somewhat greater than that of tin and its heat conductivity is exceeded only by silver, gold and copper. When its specific gravity is taken into consideration, its price per unit of volume is now one-half that of tin.

Magnesium is ductile and may be worked at temperatures between 300 and 400 deg. C. It may also be rolled into sheets, drawn into wire and produced in many commercial forms. As these and many other uses are future possibilities rather than present applications they need not be discussed here. Its use as a deoxidizer of other metals and alloys, however, is widespread and is helping in no small way to win the war.

## A Statistical Summary of Tin

A Review of the Development of the Economic Uses of Tin—History of Its Commerce—Production, Consumption and Average Prices—Measures Taken to Reduce Consumption

BY EDITH M. MILLER

Statistician, National Bank of Commerce in New York

AT THE inter-allied conference recently held in London it was decided to allot to the United States about 80,000 tons of pig tin or two-thirds of the world's entire production annually. Thus was our preëminence as a tin consumer recognized. Tin has been known to man from prehistoric time. The introduction of the use of tin as an unalloyed metal took place at a much later date than its first use as a constituent of bronze. When it was first recognized in the pure form is not known, but we do know that its Latin name, stannum, took final form in the fourth century, and that tin was imported from Cornwall into Italy after the Roman invasion. Increase in the production of tin and in its use has taken place gradually through a long period of time. During the eighteenth century the world's supply of tin was mainly drawn from the deposits of England, Saxony and Bohemia. The total amount produced, however, cannot have been very large, for in 1801 but 2,500 tons were produced in England. The nineteenth century witnessed the predominance of the English mines, whose output remained at about 10,000 tons for the most of the last half of the century. During the last decade of the nineteenth century, however, the yield in Cornwall declined very much and since 1900 has been around 5000 tons annually.

In the opening decades of the nineteenth century supplies began to be drawn from the Island of Banca in the Dutch East Indies. Billiton became of note in 1863 with a production of 40 tons. The Straits Settlements became an important producer in 1870 when the total amount mined there was 2337 tons. At the present time the chief producing regions of the world are the Straits Settlements, Bolivia, Dutch East Indies, notably Banca and Billiton, South Africa, Cornwall, China and Australia. The Straits Settlements produces approximately half of the entire output of the world.

### USES OF TIN

The uses to which tin is put in modern industry are very numerous. The largest single demand for tin comes in the manufacture of tin-plate and terne plate. Tin-plate is used for making receptacles of all kinds—kitchenware and containers for a great variety of products, both food and non-food.

The greatest single source of demand for tin-plate is for food containers. In 1914 the amount of tin-plate used for food cans and cups was sixty-five per cent of the total tin-plate manufactured. Estimates for 1917 indicate that at least seventy-five per cent was so used during that year. The process of canning was discovered in France in 1810 by Nicholas Appert of Chalons-on-Marne, and throughout its development has been

intimately associated with the waging of war. This form of food preservation was conceived primarily as a military measure to secure better stores for the army and navy. The canning industry began in France and the British Isles almost simultaneously, and was brought soon after to the United States, where it has attained its highest development. Very little progress was made in the industry prior to 1855 in this country, the principal pack being sea-food. It was during the decade of the Civil War that the superiority of canned foods over those which were dried, salted and pickled became common knowledge. The soldiers in detention camps and hospitals, although they were supplied with very small quantities, realized the excellent values of canned foods and carried the knowledge home.

The necessity for the preservation and shipment of a great variety of food products to the armies in France, both our own and those of our allies, has again caused an expansion of the canning industry and has rendered the tin supply a question of vital interest because of its intimate connection with the prosecution of the war. One-tenth or more of the tin-plate used in the United States for packing food goes into cans for condensed milk and evaporated milk. This ratio has not been increasing to any marked degree because the increase in other branches of food canned has almost kept pace with the increase in tin-plated milk production. For his canned milk alone it is estimated that each soldier will require five pounds of tin-plate per year.

Tin and tin-plate also have other important uses from a military standpoint besides the necessity for food containers. Tin-plate is used for cans for carrying gasoline to the front, for cases for shells etc. A considerable amount of babbitt metal containing tin is used in certain bearings in naval and other military machinery. It was to secure an adequate supply of tin for Government war work that tin stocks were commandeered in this country at various times during the winter.

Terne-plate is prepared with an alloy of tin and lead and is largely used in metal roofing. In addition to the alloy used to make terne-plate there are a number of other important tin alloys; bronze, for instance, is an alloy of tin and copper; babbitt metal, used in the bearings of machinery, is an alloy of copper, antimony and tin; and pewter is composed of various mixtures of tin with other metals.

Tin is used likewise to weight silk and in the manufacture of tin foil, parts of motors and machinery, wire, rubber, and chemicals. Many other industries use tin in small amounts as alloys or otherwise. Although their demand is not large, tin is none the less indispensable to their uninterrupted operation.

The increase in the production and consumption of tin in the last twenty years has been tremendous. In 1897 the total production of the world was 73,499 tons. In 1907 it had increased to 92,290 tons, while in 1917 the world's production was 120,918 tons, an increase of 65 per cent in twenty years.<sup>1</sup>

#### RELATION OF U. S. TO WORLD SUPPLY

Although the United States is the greatest consumer of tin in the world, tin in commercial quantities is not produced within our borders. Alaska produced ninety-one gross tons in 1915 and one hundred twenty-five gross tons in 1916. Beyond this very limited Alaskan output, our tin production is entirely negligible, although there are a few scattering deposits in a number of states. The problem of our tin supply, therefore, is the problem of the world's tin supply and our relation to it as a buyer in the international market.

Straits tin is by far the largest factor in the world's

The great bulk of tin produced in the Peninsula comes from the Federated States. The Straits Settlements, however, occupies the dominant position in tin output, because of the enormous smelting industry which has been built up at Singapore and Penang for the reduction of ore mined in that part of the world. In addition to the tin obtained from the extensive mining operations in the Federated and Non-Federated States, large quantities of tin ore are imported into the Straits Settlements for smelting purposes from the Dutch East Indies, Siam, Australia, and other tin producing countries. The tin actually mined in the Peninsula in 1915 amounted to 50,876 tons and in 1916 to 48,253 tons. Comparison with Table II shows that the exports from the Straits Settlements exceeded the production in the Peninsula by 17,913 tons in 1915 and 16,948 tons in 1916.

A growing interest in rubber production in which there have been very large profits is said to have seri-

TABLE I—WORLD'S TIN SUPPLIES (a)

(c) 1,300 tons to Europe, 1,500 tons to United States.

(d) Partly estimated.

(e) Arrivals in the United States.

market. Next in importance is Bolivian tin, while Banca tin is third. There are also Chinese, English, Australian, and South African tin, but they have always been regarded as of minor importance.

The United Kingdom, through her intimate connection with most of the important producing regions, is in a dominant position as to the tin market of the world. The Straits Settlements, Australia, South Africa and Cornwall, both as to tin production and shipment, are all British controlled. In 1917 the tin from these sources comprised sixty-two per cent of the entire world output.

With the exception of England, the regions from which the world's supplies of tin come are not consumers of tin, and the record of their shipments is the index to their production. Table I, therefore, indicates with approximate accuracy world tin production from 1908 to 1917:

The tin output of the Malay Peninsula, including the Straits Settlements and the Federated Malay States, is so important that it deserves special attention. The combined output of the British possessions and protectorates in this region amounts to over half of the world's production. The output of each of the important producing regions has varied considerably in the last decade, but the total production has increased rather steadily, the increase for the ten years being sixteen per cent.

<sup>1</sup>*Metal Statistics*, 1918, p. 253; also *Mineral Resources of the U. S.*, 1904.

ously curtailed production in certain of the States. Large numbers of coolies have been attracted to rubber estates by higher wages, thus decreasing the available supply of mine labor.

Table II gives the exports of tin from the Straits Settlements, by principal countries of destination, for the years 1915 and 1916, according to the official returns:

TABLE II—TIN EXPORTS FROM STRAITS SETTLEMENTS (a)

| Destination             | Quantity (Gross Tons) |        | Value        |              |

(a) U. S. Commerce Reports, October 8, 1917.

The tin which comes to this country is chiefly in the form of bars, blocks, pigs, or grain and granulated tin.

The country from which tin is imported, according to the return of the United States Bureau of Foreign and Domestic Commerce, is not necessarily the country of origin. Imports from the Netherlands are re-exports from the Dutch East Indies. Similarly, a considerable amount of the tin shipped from the United Kingdom is Straits tin, or the product of other mines which has come through British ports. In 1917, sixty per cent of our tin was mined in the Straits Settlements, sev-

enteen per cent in Banca and Billiton, and eleven per cent in England.<sup>2</sup>

Table III shows the imports of tin into the United States by countries, from 1908 to 1918, inclusive. In this table our importation of tin ore is not included:

TABLE III—IMPORTS INTO THE UNITED STATES, 1908 TO 1917 (a)

| Year | Germany | United Kingdom lands | Netherlands | (Gross Tons) Dutch East Indies | Straits Settlements | Hong-kong | Australia | All Others | Total  |
|------|---------|----------------------|-------------|--------------------------------|---------------------|-----------|-----------|------------|--------|
| 1908 | 659     | 24,650               | 244         | ..                             | 8,600               | 14        | 76        | 264        | 34,507 |
| 1909 | 975     | 24,142               | 335         | ..                             | 14,816              | 151       | 170       | 91         | 40,680 |

(b) No method of determining whether included in "All Others"

It will be observed that our imports of tin increased steadily from 1908 to 1913. In 1914 and 1915 there

TIN MINE, BOLIVIA

was a decided falling off. In 1916, however, our imports not only recovered, but exceeded all previous records. In 1917 and in 1918 our imports declined from the high level of 1916 but were substantially greater than in 1915 or any preceding years. The effect of the war on shipping routes, which will be discussed later, is clearly shown in the above table. Prior to 1914 we received no tin directly from the Dutch East Indies, but received it by way of the Netherlands. Since the war the Dutch East Indies has been shipping to us directly.

Interesting to note is the fact that while in 1914 our importations of tin from the United Kingdom and from the Straits Settlements formed 90 per cent of the total, in 1918 they amounted to only 63 per cent of the total. The loss was in a large degree offset by heavier shipments from Hongkong, Australia and the countries not separately shown.

It should be noted that total imports of metallic tin for 1918 including the tin content of the ore imported, were said to set a new high record and to total 69,731 tons as compared with 67,529 tons in 1916. Our importation of tin ore previous to the fiscal year 1916 was so small that it was not reported separately by the Bureau of Foreign and Domestic Commerce. Owing to the absence of smelters in the United States, until very recently we could not bring South America

tin direct from the Bolivian mines. Instead, ore had to be shipped to Europe or the East for smelting before any of it found its way into the markets of this country.

In the fiscal year 1916, 5415 tons of tin ore were received from South America, and two tons from Panama. During the fiscal year 1917 we imported 5120 tons, and in 1918, 14,816 tons. According to figures recently compiled by the Bureau of Foreign and Domestic Commerce, our 1918 tin ore imports were equivalent to 8,785 tons of metallic tin and thus "approximately 13 per cent of our 1918 imports came to us in the form of ores, mostly from Bolivia."

#### WORLD CONSUMPTION

It is not possible to get exact data on tin consumption, but the amount of tin stocks in the chief markets of the world may be compared from year to year. Such comparison should serve at least to show whether production is increasing faster than the demand for tin, or whether tin stocks are being depleted through a rate of consumption faster than the rate of production.

Table IV shows stocks of tin in London, Holland and the United States (exclusive of Pacific ports) at the close of each month, from 1913 to 1917, inclusive. The stocks fluctuate widely, but it can be seen that there is no very marked tendency towards an increase or a decrease. The consumption is evidently about keeping pace with the production, and *vice versa*.

TABLE IV—WORLD'S STOCKS OF TIN (a)

| Month     | 1913  | (Gross Tons) 1914 | 1915  | (b) 1916 | (b) 1917 |

(b) Includes stocks at U. S. Pacific ports.

#### TIN CONSUMPTION IN THE UNITED STATES

A decided increase in our tin consumption took place in 1916 and 1917.<sup>4</sup> This increase is not only absolute, but the percentage of the world's consumption which was consumed in this country increased from forty-two per cent in 1915 to fifty per cent in 1917. Whether this is a temporary condition which will readjust itself after the war is impossible to predict, but the war has evidently caused a lessening of the manufacture of tin products in Europe and a corresponding stimulation of the industry in this country.

At the present time, a much larger share is consumed by this industry. Exact data are not available, but it is likely that the quantity so used approximates two-fifths of the total amount of tin used in manufactures in this country. Before the war, during 1912 and 1913, about one-third of the total amount of tin consumed was used in the production of tin plate. Our production of tin-plate, terne plate, and taggers' tin, has increased from 1,153,097,000 pounds in 1908 to an estimated 3,360,000,000 pounds in the calendar

<sup>1</sup>U. S. Commerce Reports, July 31, 1918.

<sup>2</sup>Metal Statistics, 1918, page 259.

<sup>3</sup>Metal Statistics, 1918, page 269.

year, 1917. Our net imports have declined so as to be almost negligible, while exports for 1917 are over 15 times what they were in 1908. There was no great increase in tin-plate retained for consumption up to 1917 but during the year just past, our consumption of tin-plate increased very decidedly, the consumption for the year 1918 exceeding that for the year 1917 by more than twenty-five per cent.

Table V shows the marked increase in our tin-plate industry:

TABLE V—TIN PLATES, TERNE PLATES, AND TAGGERS' TIN (a)

| Year Ending<br>June 30 | Production<br>(In Thousand Pounds)<br>(b) | Exports | Net<br>Imports | Total Retained<br>for Consumption |

| 1916                   | 2,365,296                                 | 516,257 | 1,789          | 1,850,828                         |
| 1917                   | 2,766,400                                 | 521,861 | 1,358          | 2,255,897                         |
| 1918                   | (c) 3,360,000                             | 563,068 | 71             | 2,797,003                         |

(a) From a Statistical Abstract of the U. S. and June, 1917, Summary of Foreign Commerce of the U. S.

(b) Production is for the calendar year preceding the fiscal year.

(c) Estimated, from *Iron Age*, Jan. 3, 1918, page 65

Our net imports, that is to say, the difference between our total imports of tin plates, terne plates and taggers' tin, and the amount of tin foreign plates and taggers' tin were not very large as compared to our production in any of the years shown in the table, but they have fallen off very markedly since the outbreak of the war.

The expansion of our exports is primarily due to the fact that those European countries normally producing tin-plate for export have been compelled by the war to apply their productive efforts in other directions.

The manner in which the United States has taken advantage of markets thus available is shown by Table VI:

TABLE VI—U. S. EXPORTS OF TIN PLATES, TERNE PLATES, AND TAGGERS' TIN, 1908 TO 1917 (a)

| TABLE 4. COUNTRY OF ORIGIN OF THE VESSELS, BY VESSEL TYPE, AND TONNAGE TON, 1908 TO 1917 IN |        |                            |                   |        |               |        |                  |              |         |  |

(a) From U. S. Bureau of Foreign & Domestic Commerce, Commerce and Navigation of the United States, 1911, 1916, and Monthly Summary of Foreign Commerce of the U. S., June 1918.

Considerable irregularity is to be noted in our tin-plate exports up to and including the fiscal year 1915. Exports for 1916, however, amounted to three times the total for 1915. Canada is and has always been our single largest customer for tin-plate, but the increase in our exports to Canada was not so marked between the outbreak of the war in the fiscal year 1915 and in 1916 as was the increase in exports to the United Kingdom, to Japan, and to British India.

Export license requirements discussed elsewhere went into effect on Oct. 24, 1917. In spite of these restrictions our exports for the fiscal year ending June 30, 1918 increased eight per cent to 251,371 tons over the exports in the preceding fiscal year. We exported

less tin and terne plates and taggers' tin to Canada, the United Kingdom, China and British India, but more to Argentina and Brazil, Hongkong, Japan, and the countries grouped in the classification "All others."

#### INTERNATIONAL RELATIONS

Under an agreement recently reached by representatives of the United States, Great Britain, France, and Italy at conferences held in London, each of these countries will get its needed supply of pig tin. The action amounts to an international monopoly of a beneficent nature.

The plan of distribution worked out allows the United States about 80,000 tons of pig tin or two-thirds of the world's entire production annually.

With the War Industries Board supervising the allowance to this country, all imports of pig tin, in ores and concentrates will be assigned to the American Iron and Steel Institute which will receive pay for and distribute the metal to the industry through the United States Steel Products Co.

The price will be regulated by the War Industries Board and will be uniform to consumers of 10 tons of pig tin or over. There will be another uniform price for users of less than 10 tons. These prices will be maintained at a level which will encourage production in the tin mining countries—Great Britain and the Straits Settlements chiefly—and stop profiteering. Prices, rules, and regulations will be announced later. It is probable that users and dealers may be licensed.

The War Industries Board believes there will be insured by these arrangements a steady supply of material at a stable and reasonable price. Since the negotiations for the pooling arrangement began in London six weeks ago the price of pig tin has fallen steadily. The quo-

tation of Sept. 6 last showed a net decrease of 14 cents per pound as compared with the price on July 15, 1918.<sup>a</sup>

Within the last year complications with Holland have threatened to tie up tin shipment from Banca and Billiton. On April 22, 1918, Holland imposed an export license on tin and tin ore leaving the Dutch East Indies, but it is understood that this is not at present to interfere with traffic with the United States.

#### GOVERNMENT CONTROL

The export of tin-plate from the United States was first restricted by regulation of the War Trade Board

<sup>a</sup>Official Bulletin, September 11, 1918.

announced on October 24, and amplified on November 12, 1917. According to these rulings, all exports of tin plate and articles containing tin were placed under license, whose issuance was carefully regulated by the proof in each case as to the use to which the goods were to be put. Preference was given for the exportation of tin-plate for use for any other purpose than as food containers, or of articles other than tin-plate, containing tin, except on satisfactory evidence that the goods would be used in such a way as to contribute to the military needs of the nations at war with Germany and her allies. Licenses might be granted for the exportation of articles other than tin-plate containing tin, if the goods would be used to contribute to vital needs other than military of the nations at war with Germany and her allies. No license was to be granted except to manufacturers, or others who could present satisfactory evidence that they had purchased the plate from a manufacturer on firm order from a purchaser abroad.

On March 6, 1918, further restriction on the exportation of tin and terne-plate was announced by the War Trade Board, with the object of directing the supply

VICTORIA CONCENTRATING WORKS, AUS TIN MINE

for the benefit of the allies. The rules announced supplement those already in force and are as follows:

Licenses may be granted to manufacturers of tin-plate and terne-plate or to persons other than a manufacturer, provided the purchase of the plate has been made directly from a manufacturer prior to November 12, 1917, and also provided such purchase has been made to fulfill a contract or firm order from a purchaser abroad placed with a firm in the United States, a copy of which must be annexed to the application. Export licenses for tin-plate or terne-plate may be granted only for shipment to Canada, South and Central American countries, including Mexico and the West Indies, China and Japan, and only when the plate is to be used either—

1. To manufacture containers for edibles for human consumption by the people of the nations at war with Germany and her Allies, or
2. To manufacture oil cans, provided the plate has been ordered from the mill on or before August 27, 1917. In this case there shall be no distinction between purchases from manufacturers and purchases from others, or
3. When the plate is to be shipped to any of the above mentioned countries except Canada, it is to be used for purposes which shall contribute directly to the successful prosecution of the war, or
4. When the plate is destined for Canada it is to be

used for purposes for which tin-plate or terne-plate is now permitted to be used in the United States.<sup>1</sup>

Despite these regulations, export figures, as already noted, indicate no noteworthy reduction in our exports of tin-plate. Exports to the Allies constitute an essential part of the war programme. For example, the French Government has proposed an exchange of services for 1918 whereby France will undertake to pack enough canned goods for herself and for the American forces abroad, provided the United States will furnish the tin-plate. The labor will largely be performed by women and it is estimated that the saving in ocean tonnage will be considerable. Exports to neutrals, and to countries not actively assisting the Entente Allies in the prosecution of the war totalling perhaps 50,000 tons for the fiscal year just closing, are difficult of explanation in the face of the apparent tin shortage.

In the absence of Government price control, tin prices have naturally reflected the scarcity which has existed for so many months, both in this country and in England. Prices have gone far above all previous records. In this country the virtual absence of spot tin has made price a more or less theoretical question, but it is safe to say that tin prices have doubled in the last two years.

Table VII shows the trend of tin prices on the London market for the years 1911 to 1917, inclusive:

(b) Market strictly nominal December 12 to 31; 86.00c. used for those dates as arbitrary basis in computing the month's average.

<sup>1</sup>New and more complete regulations were issued by the War Trade Board (W.T.B. 203) too late to be included in this article. The changes from the above consist mainly in classifying the exports and giving specific instructions as to procedure.

food packing industry was recognized in the Spring of 1917 and, by voluntary agreement, packers of non-perishable foods stopped running during June and July in order to insure an adequate supply of tin cans for the perishable crop then coming on. Since that time conservation in various directions has been urged and, to a degree, has taken place.

The conservation of tin plate is of prime importance. According to the War Trade Board, "That there may be a sufficient supply of tin in the United States to meet the war needs and to supply essential civilian uses, vigorous plans for conservation of the metal are being made effective through coöperative efforts by the War Industries Board and by the Food and Fuel Administrations in the enforced substitution of other than tin containers, wherever that is possible. Tin container manufacturers have agreed with the War Industries Board in plans that will curtail their use of tin plate 13 per cent which means a saving in the next three months of about 150,000 tons of tin plate.

The Food Administration is working out a tin conservation plan with various industries, including lard and lard compound packers, wholesale grocers, cracker manufacturers, tea and coffee packers, cocoa and chocolate manufacturers, and baking-powder manufacturers. All have been urged to substitute fiber, paper, or other containers where possible.

The Fuel Administration has taken up the subject with the oil dealers and the War Industries Board is working along similar lines with the tobacco manufacturers and all industries in which tin is used in turning out the finished product.<sup>6</sup>

The substitution of other materials for tin containers has gone much further abroad than it has in the United States, and the possibilities in this direction are great. During August, 1917, a cardboard container was developed in Great Britain for use in packing army jam. Since that time its manufacture has been so developed and extended that there is now an output of 5,000,000 cardboard containers per week. The bulk of these are two-pound size, but a proportion are of one-pound and five-pound sizes and all three are used as substitutes for tin packages. Since last September, in Great Britain, dried foodstuffs and semi-liquid foods have not been "permitted to be packed in tin-plate, nor has fruit. The use of terne-plate for lining packages for the export of textile and other goods has also been prohibited, and where use of tin-plate could not be wholly stopped, economies were attempted by insisting upon the use of larger containers for packing meat and canning milk. The size of oil cans was doubled, and in India tin-plated iron drums were brought into use for petroleum products.

"At the present time tin containers are practically used only for meat and processed foodstuffs. Most of the paper or cardboard containers employed have been largely of the kind known as composite containers, i.e., having tops and bottoms of tin, but it is expected to soon perfect the manufacture of these containers so as to be able to make them all paper products.

"Efforts have been made to introduce substitutes in the army. Cardboard, wood and fiber are now substituted for tin-plate in the manufacture of such things

as card-index boxes and workmen's checks, while earthenware bowls are used instead of the old pudding bowls. Salt, sugar and tea, which formerly were packed in soldiers' rations tins, are now packed in paper bags. Recent regulations of the Ministry of Munitions have put the civilian trade upon a very strict ration, so that there will only be a bare minimum supply of essential articles, such as domestic utensils, stoves, meters and lamps."<sup>7</sup>

While this saving in tin-plate in Great Britain has been primarily for the purpose of conserving steel rather than tin, the result has been to save a large amount of tin.

The Australian Government has forbidden the use of tin-plate for the making of many articles, chief of

SMELTING WORKS AT MIRAFLORES, UNCLIA

which are the containers for boiled sweets, for packing butter in quantities less than two pounds, except for war purposes and for dispatch to soldiers abroad, for the making of second lids for containers of butter and cheese and for use in the manufacture of stoves, phonograph horns and kerosene pumps. That Government has also forbidden the replenishing of stocks of articles made of tin-plate more than is necessary for three months' use, and has forbidden the importation of a number of articles made of tin plate and of many other articles when packed in tin plate.

Reduction of the amount of tin used for purposes other than the manufacture of tin-plate has not been overlooked.

The quantity of tin absorbed in the manufacture of silks is so large that the Government is taking cognizance of the fact. The tin used for this purpose is largely recovered metal, converted into tin tetrachloride and sold to silk dyers for weighting and finishing the fabric. The aggregate amount of tin per year used in the United States for the weighting of silk is not known, but estimates of as much as five thousand tons have been made. The use of tin for weighting is detrimental to the wearing qualities of the silk, and is the chief cause of cracking. It is the purpose of the Government to reduce the amount of tin used in the silk industry to a minimum.

The substitution of lead-base babbitt metal for tin-base babbitt metal, and the reduction of the tin content

<sup>6</sup>Official Bulletin, September 11, 1918.

<sup>7</sup>Journal of Commerce, N. Y., July 15, 1918.

of the tin-base babbitt metal is being urged, as well as economical use of babbitt metal. The Bureau of Standards has completed an investigation of bearing metal and has suggested elimination of all but four grades. It is stated that a saving of about 25 per cent in amount of tin will be affected. Large savings have already been made by automobile and other machine manufacturers by substituting for all metal bearings, case bearings with thin lining shell  $\frac{1}{16}$  to  $\frac{3}{16}$  of an inch high grade babbitt. Straits tin is often specified on the assumption that it is the purest tin. Banca is even purer than Straits or Australian, and electrolytic tin is as pure.

Reduction of the percentage of tin in alloy castings to the lowest possible figure is being advocated, and the substitution wherever possible of a mixture of lead and tin solder for pure tin solder. The Bureau of Standards is making investigation of solder along the same lines as its investigation of babbitt metal. It is stated that "the can companies have reduced the percentage of tin in their solder to forty, thus saving eight to ten per cent without injury to the industry."

"A plan was suggested and is now being perfected for the recovery of a large part of the tin used in foil and tubes. Through a campaign of advertising through notices on the packages and other methods, consumers of articles packed in foil or tubes will be induced to save those articles and turn them in at the nearest Red Cross center as donations. Smelters and other users of tin will then purchase at market rates the lots thus collected by the Red Cross. It is estimated that this will recover some 3000 to 5000 tons of tin per annum and bring the Red Cross an added income of from \$4,000,000 to \$5,000,000."

The possibility of the utilization of empty cans and of the tin in them is also being considered. Oil cans sent from this country to the Orient have been used there for some time in making an inconceivable number of articles—lamps, cook stoves, pots, pans, sprinklers, toys, bottle caps, dust pans etc. The possibility of a notable saving in this country by a similar utilization is now being considered. The Department of Commerce has urged upon State Councils of Defense, Chambers of Commerce and other trade organizations the consideration of the collection of old tin cans before they have rusted, in order to sell them to tinning companies. It is hoped that a considerable amount of tin can thus be recovered. The Food Administration has also advocated the straightening and retinning of dairy cans as a means of saving the tin-plate. Such cans can be renewed at from one-fourth to one-third the cost of new ones.

#### SHIPPING ROUTES FOR TIN

Prior to the war, London was the center of the tin trade of the world. The ruling prices on the London market governed the value of all other grades of tin. Great Britain controls not only Singapore and Penang, from which Straits tin comes, but the Chinese product, which is shipped from Hong Kong. Her control was complete at these ports, not only because of political dominance, but because nearly all the vessels in the tin trade were of British register.

Great Britain made it a definite policy to confine the tin trade as far as possible to London, and for this

reason all consignments destined from Singapore or Penang for America had to come via London, and thence across the Atlantic, though the direct route would have been via the Pacific to San Francisco. Bolivian tin is partly smelted in that country, but prior to the erection of tin reduction works here, much of it was sent to English smelters, and thence to the United States.

The increasing facilities for smelting the tin here will effect an important economy in this shipping. It is reported, moreover, that the Tin Committee of the Council of National Defense has arranged for the direct shipment of tin from the Straits Settlements to the Pacific coast.

Tin, even after it arrived in this country, was customarily subjected to unnecessary shipments. Consignments arriving at the Pacific coast would be bonded to New York, cleared at the Custom House there, and often shipped half way back across the continent to consuming points in the Middle West. The practice was not only expensive, but it led to considerable congestion at the terminal points in New York and to traffic delays in the journey. To reduce such difficulties to a minimum, the Sub-Committee on Pig Tin of the American Iron and Steel Institute has recommended to the tin trade that consignments be passed through the Custom House at the Pacific ports or, if this be impracticable, that they be shipped in bond to Chicago, Pittsburgh, or other convenient points of distribution.

Only once before the beginning of the war had our total imports of tin exceeded 50,000 tons. This was for the fiscal year ending June 30, 1913, when we received 51,213 gross tons. Our average imports for the five fiscal years preceding the outbreak of the war were less than 50,000 tons.

Our total imports of metallic tin for the fiscal year just ended amounted to 69,731 tons, the highest figure in our history. The inter-aliied pooling agreement in allowing us 80,000 tons annually seems to have provided amply for our needs. Of course, the fact that this country has been "allowed" 80,000 tons does not necessarily mean that we will import that much tin. Nevertheless it is an indication that a more plentiful supply may be expected. Normal conditions cannot be hoped for until the close of the war, but reasonable conservation and skillful distribution may be expected to meet the present situation so successfully as to minimize the effects of the disturbing factors which are now affecting the supply of and demand for tin.

---

**Bolivian Tin Profits.**—The gross profits of the Llalagua Tin Company, of Bolivia, for 1917 was £1,712,170, against £466,123 in 1916, the dividends distributed absorbed £637,500, while £850,000 was allocated to future dividends. The capital of the company is £425,000, the interest and dividend reserve total £850,000, and other reserves £466,000. The production of concentrates increased from 7460 long tons in 1916 to 11,250 tons last year. The costs of production, etc., were less in 1917 than in 1916, being last year about £36 a ton in 1916. The largest increase was shown by the Llalagua Company, which ranks second as a producing company, being surpassed only by the Patino Company, whose last year's output was 13,300 tons of concentrates, against 10,000 tons in 1916.

## Testimonial to Dr. M. C. Whitaker

WHEN Dr. Milton C. Whitaker retired from the presidency of the Chemists' Club his fellow officers and trustees gave him a silver service in appreciation of his remarkably able administration of the club's affairs. Inasmuch as there was a surplus left after the purchase of the silver, Messrs. Ellwood Hendrick, the succeeding president, Thomas R. Duggan, chairman of the house committee and Dr. Bernhard C. Hesse, conceived the idea that it would be well to add something more personal with the remainder. With the consent of the donors they engaged Mr. Edward B. Edwards

emblem of the Chemists' Club, a benzene ring enclosing a salamander and a flame. The alchemistic symbols in the border beginning at the upper left hand corner and reading around to the right, are as follows: Gold, Fire (Chemists' Club Emblem), Air, Silver, Copper, Tin, Sulphur, Water, Vitriol, Mercury, Lead and Iron. The scheme of decoration is a very happy one and lends itself to the embellishment of halls and buildings devoted to chemistry.

Traditions are beginning to appear at the Chemists' Club. There is a little copper container for coffee which has engraved upon it "The President's Pot," presented a couple of years ago by Mr. Lane of the

to design the memorial of which we give an illustration herewith.

It is framed so that both sides may be seen, the reverse containing the record in English and the names of the donors. The beautiful Latin text is from the pen of Professor McCrea of Columbia University. The English text, which is freely translated, reads as follows:

We, your fellow officers and trustees of the Chemists' Club during the term of your presidency, recognizing your great service in directing its affairs with signal ability and rare foresight, present this minute of our sincere appreciation.

New York, May 1st, 1918.

The memorial is of peculiar interest in that alchemistic symbols are employed in the decoration. In the four corners are vignette portraits of Geber, Roger Bacon, Raymond Lully and Paracelsus copied from an old French work. In the centre of the top border is the

U. S. Appraisers' laboratory, to distinguish the incumbent of the presidential office. Dr. Whitaker refused to turn it over on his retirement without, as he declared, the proper ceremony, and he lately invited the trustees to dine with him at the club before their meeting, to witness him endow it upon his successor for the term of his incumbency.

On receiving his official decoration President Hendrick responded as follows:

This copper Presidential Pot  
Is singular in that it's got  
The function of entailment meant  
For each succeeding President.

Now let's engrave upon it well  
The name of Whitaker to tell  
That it was he who was the first  
To quench his presidential thirst  
From it, when as he broke his fast,  
And also, when the day was past,  
To fill from it his little cup  
To live his digestion up.

Then underneath we lesser men  
May follow him as now and then  
We serve each one his little day  
And, having done so, fade away.

This pot, from which I hope to drink  
My fav'rite coffee, black as ink,  
Is mine in trust but for the span  
That I'm entitled to the can.  
It is not part of my estate.  
And yet I certainly should hate  
To have it used by any slob  
So long as I hold on my job.

This is not spoken as a threat  
Because I've hardly got it yet.  
I merely mention it because  
It is not written in the laws  
And I don't want to strew my path  
With tokens of unholy wrath.

And now I offer you this toast  
For those who really need it most:  
May every one who stays his thirst  
From this pot, emulate the first  
To use it. May he stir  
The Club's dry bones like Whitaker,  
Employing wisdom, judgment and  
The requisite amount of sand,  
Without once ever letting slip  
His standard of good fellowship.

## From A to Z With the Exhibitors

**PROVOST ENGINEERING COMPANY.** Filter presses. Particular developments since the United States entered the war are special filter presses for acids. In charge of exhibit: J. A. NAUGLE, C. A. BEACH.

**QUIGLEY FURNACE SPECIALTIES COMPANY, INC.** Demonstration of the use of hyseltite furnace cement, in a small high-temperature electric furnace. A new insulating brick will also be thus demonstrated and samples of Kieselguhr will be shown. In charge of exhibit: W. S. QUIGLEY, C. P. GANTZMAN, F. J. SPILLANE, J. H. MCPADDEN.

**RARITAN COPPER WORKS.** Products showing the various stages of smelting and refining copper from the ore to commercial bars, together with by-products of the electrolytic refining of copper bullion, such as nickel sulphate, copper sulphate, selenium, tellurium, silver, gold, palladium and platinum. Anaconda electrolytic zinc, common copper, corroding lead and an antimonial lead will also be shown. The production of electrolytic pure zinc has been accomplished since the war began, and has had an important bearing on high-grade munitions. In charge of exhibit: S. SKOWRONSKI.

**RAYMOND BROTHERS IMPACT PULVERIZER COMPANY.** A full line of pulverizing machinery equipped with air separation. Three of the models are one-quarter size of the actual mill, but the fourth will be of the actual size such as is used in the chemical, dry color and dyestuffs industries. All will be in operation in such a way as to show the actual workings of the mill for any particular purpose. In charge of exhibit: R. A. LACHMANN.

**RESEARCH CORPORATION.** A complete set of samples of the different materials collected by the Cottrell processes, so arranged to indicate the use of processes in particular industries. Special emphasis is laid on the use of the processes in connection with those industries that are vital to the prosecution of the war, such as acid plants, steel works, potash recovery plants, etc. Since the beginning of the war the use of the processes in the sulphuric acid industry has been greatly expanded

and has been successfully applied to the cleaning of hot sulphur dioxide gases from roaster furnaces and for the recovery of acid mist from the exit gases from concentrators. The application of the processes for the cleaning of iron blast furnace gases, which is a successful means of recovering potash, manganese and other valuable constituents. In charge of exhibit: H. D. EGBERT.

**REVOLVATOR COMPANY.** Revolving and non-revolving types of the revolver. This equipment is of unusual interest at the present time in view of the labor shortage for handling materials. The Government requirement of piling materials to the roof of box cars has opened a new field for this device.

**ROESSLER & HASSLACHER CHEMICAL COMPANY.** Chemicals used for electro-plating, case-hardening and heat treating, principally cyanides. There will also be a display of such materials as steel, copper, silver and bronze which are plated, treated and finished with the company's chemical products. In charge of exhibit: Doctor ABEGG.

**ROSSENDALE-REDDAWAY BELTING & HOSE COMPANY.** Illustrations of drives on which the company's belts are used, and showing the conditions which have to be met in various plants. Some of these belts will also be shown in operation to illustrate features of special interest to the chemical industry. In charge of exhibit: WILLIAM L. CLARKE.

**RUGGLES-COLES ENGINEERING COMPANY.** A model of a double-shell direct-heat dryer, together with diagrams of different installations of the various types of dryers manufactured. In charge of exhibit: F. E. FINCH.

**THE R. U. V. COMPANY, INC.** A quartz mercury-vapor lamp and an ultra-violet ray laboratory outfit using this lamp as the source of ultra-violet rays. New features of the outfit will be shown. In charge of exhibit: Mr. RICORD.

**SCHAEFFER & BUDENBERG MANUFACTURING COMPANY.** Indicating and recording gages of all types, gage testers, indicating and recording thermometers, "reform" mercury actuated dial thermometers, hand and stationary tachometers, counters, steam calorimeters, etc. As a special attraction there will be an exact reproduction 9 ft. high of an industrial thermometer which in reality only measures 14 or 15 in. high. In charge of exhibit: H. V. KARLIER F. UNDEUTSCH, A. WEISS.

**SCHAUM & UHLINGER.** Nirtol cellulose extractors and a laboratory centrifugal. In charge of exhibit: C. W. SCHAUM, A. J. CADY, L. GRISCOM.

**SCHUTTE & KOERTING COMPANY.** A display of power plant equipment including injectors for boiler feeds, emergency safety valves, non-returns and a complete line of fuel-burning equipment; apparatus used in the chemical industry for handling corrosive gases or liquids, such as steam jet exhausters and compressors, ventilators, blowers and hard-lead fans, also pumping equipment such as syphons, air jet lifts, centrifugal pumps and automatic blowcases. There will also be spray nozzles of numerous types but particularly the Witclay sulphuric chamber nozzle. A new development since the war began is the Bihn-Jones automatic attachment for blowcases. In charge of exhibit: C. H. KIMBERLY.

**SCHWARTZ SECTIONAL SYSTEM.** Equipment for systematically arranging and instantly locating chemicals,

reagents, samples, and similar materials which may be kept under ideal conditions free from dust and away from the detrimental effects of light.

**SCIENTIFIC EQUIPMENT COMPANY.** An exhibit of laboratory instruments and apparatus and laboratory furniture made by the Central Scientific Company and the Kewaunee Manufacturing Company. In charge of exhibit: O. T. LOUIS.

**ERNEST SCOTT & COMPANY.** Photographs of plant and machinery installed by the company for chemical processes, showing evaporators for various purposes; solvent extraction plant for recovery of grease and oil; caustic recovery plant; glycerine recovery plant for recovering glycerine from fats and oils; glycerine refining plant; soap plant machinery; fish drying plant; fish oil extraction plant; plants for the distillation of water, naphtha, acetic acid, crude pyroligenous acid; apparatus for degreasing skins and hides; plant for the manufacture of electrolytic caustic soda and caustic potash. New features developed since the war comprise equipment for the manufacture of pure ammonia from gas and coke oven spent liquor. In charge of exhibit: H. AUSTIN.

**SEYDEL MANUFACTURING COMPANY.** Benzoic acid and its derivatives which the company is manufacturing at the rate of over 1000 lb. per day. There will also be an exhibit of the company's furamine fur dyes together with a collection of furs dyed therewith.

**SHARPLES SPECIALTY COMPANY.** Super-centrifugal machines, and blueprints showing layouts of processes in which the machines are used. In charge of exhibit: MAX B. MILLER.

**SHAWINIGAN WATER & POWER COMPANY.** An exhibit of the industries at Shawinigan Falls, Quebec, Canada, comprising calcium carbide, carbon electrodes, magnesium metal and powder, glacial acetic acid and allied chemicals. The last-named article has been developed synthetically from calcium carbide since the beginning of the war. There will be an automatic projecting machine showing the views of exteriors and interiors of the various plants and development at Shawinigan Falls. In charge of exhibit: V. G. BARTRAM.

**T. SHRIVER & COMPANY.** Two or three of the most popular types of filter presses in as many different sizes. In charge of exhibit: I. R. E. PERRY.

**SIDIO COMPANY OF AMERICA, INC.** Fused silica ware for laboratory purposes and for use in chemical, scientific, technical and industrial operations. Combustion and pyrometer tubes in all sizes and diameters will be shown, as well as an exhibit of dishes, trays and pipes for the concentration of sulphuric acid. In charge of exhibit: G. H. MULLER, F. H. RUHE.

**WALTER SODERLING, INC.** "Dustite" respirator for protection of workers in cement plants, color plants, lead works and other industries where irritating and poisonous dust might injure the lungs and membranes of the nose and throat. In charge of exhibit: WALTER SODERLING.

**SOUTHERN PINE ASSOCIATION.** The prime chemical products derived from Southern yellow pine, with charts explaining the various chemical processes. The various finishes are illustrated in the railing enclosing the booth. Samples of the chemical products, tools and cups used in the turpentine industry will be displayed;

a model showing the commercial utilization of an average pine tree from the woods to finished products. In charge of exhibit: L. R. PUTMAN.

**SOWERS MANUFACTURING COMPANY.** A special 200-gallon full jacketed kettle with special mixer and outlet, developed for mixing 80-20 amatol; standard laboratory vacuum pans; photographs of various equipment. In charge of exhibit: C. M. DEFORREST.

**F. J. STOKES MACHINE COMPANY.** Rotary compressor in operation making naphthalene moth balls. Small rotary vacuum dryer with patented spiral agitator; dry dust filter and automatic discharge outlets; small laboratory shelf vacuum dryer with condenser and receiver forming a stand; copper vacuum still; automatic combination water still. In connection with war work this company has adapted its compressing machines to the making of pellets of TNT, tetryl, black powder and other explosives. In charge of exhibit: LAWRENCE H. BAILEY.

**STUART & PETERSON COMPANY.** Plain and porcelain lined chemical ware. The principal feature of the exhibit is the 25-gallon cast-iron enameled still representative of those which are built up to a capacity of 1000 gallons. There will also be on exhibit smaller pieces of laboratory ware. During the last two years this company has developed a large line of special apparatus, but particularly sulphonators and steam jacketed vacuum pans. In charge of exhibit: LOGAN B. MORRIS.

**STURTEVANT MILL COMPANY.** Machinery for crushing, grinding, screening, weighing, sacking, dry mixing, elevating and conveying, either in full size or working models. One of the features of the exhibit is the "open door" labor-saving accessibility of Sturtevant machinery. In charge of exhibit: L. H. STURTEVANT, H. A. TOMLINSON, W. T. DOYLE, R. M. GAY, D. KANTOR, E. M. YOUNG, J. H. WAYMAN, W. L. DOTEN.

**SWENSON EVAPORATOR COMPANY.** Evaporators, diffusion batteries, welded digesters, machinery for beet sugar plants. In charge of exhibit, S. W. HIND.

**C. J. TAGLIABUE MFG. COMPANY.** Automatic apparatus for the control of temperature, pressure, time, liquid level, and condensate. The particular controllers which have been developed since we entered the war are the automatic liquid level and condensate controllers for use on evaporators, paper drying machines, tanks and drying apparatus. There will also be an exhibit of indicating and recording thermometers, hydrometers, oil-testing instruments, hydrophants, barometers, etc. In charge of exhibit: L. C. IRWIN, B. O. PALLIN, H. T. CRUAX, T. T. DOUGHERTY, W. W. WHITE.

**TAKAMINE LABORATORY, INC.** A display of chemical specialties: Polyzime, used as a desizing agent in the textile industry; Hirathiol, Ichthylol equivalent, imported from Japan; Arsaminol and Neo-arsaminol, manufactured in this country. Among other imported chemicals shown will be potassium ferrocyanide, potassium ferrocyanide, potassium iodine, potassium bicarbonate, resublimed iodine. In charge of exhibit: C. P. CONCANNON.

**TAYLOR INSTRUMENT COMPANY.** An exhibit in three sections devoted respectively to (A) electrical pyrometers and engraved thermometers and hydrometers; (B) Tycoos industrial thermometers; (C) Tycoos recording thermometers and pressure gages and Tycoos press-

ure and temperature regulators. The pyrometer line will include indicating and recording pyrometers in single and multiple form with special switchboard completely wired and ready for use. Tycos base metal and rare metal thermit couples will be exhibited in a way to show methods of construction. The Fery radiation pyrometer will be demonstrated. Engraved thermometers and hydrometers will be shown in a complete line, with the method of manufacturing demonstrated. Oil-testing apparatus and differential thermometers will form a part of this exhibit. Industrial thermometers will be shown in a wide range of sizes and for a variety of applications. Temperature regulators and controllers will be shown in various types, from the simple controller for maintaining uniform temperatures and ordinary hot-water tanks to the more complicated instruments for regulating temperatures and controlling the time period where the temperature must be advanced by degrees to a predetermined maximum and maintained at that point. Regulators will be on exhibit especially adapted to benzol apparatus. The instruments which have been developed within the past four years, or since the war began, are U. S. Bureau of Mines pattern flash and fire testers for low-burning and high-burning oils. Gasoline distillation apparatus built according to the specifications of the United States Bureau of Mines and American Society for Testing Materials. Tycos differential thermometers constructed in a solid engraved stem pattern.

THERMAL SYNDICATE, LTD. Vitreosil ware for chemical industries and laboratory and research work. This is pure fuse silica in opaque, translucent, and transparent varieties. The features which have been developed during the past year are industrial tubes in 10-ft. lengths; large S bend cooling sets for nitric and hydrochloric acid and transparent tubing and laboratory ware. In charge of exhibit: A. A. MONFRIED, S. L. TYLER, E. J. VANVRANKEN, W. W. WINSHIP.

TOLHURST MACHINE WORKS. Five different types of Tolhurst centrifugal machines having the standard self-balancing feature. The latest type of suspended centrifugal with bottom discharge and 40-in. basket, built for specially heavy duty, will also be shown. The center-flung open-top centrifugal, developed since the war, will be shown in operation. Since the outbreak of the war this concern has developed several types of centrifugals especially designed for the rapid production of munitions. In charge of exhibit: W. C. DUTTON.

UEHLING INSTRUMENT COMPANY. Fuel-saving equipment, CO<sub>2</sub> recorders, combustion recorders, draft recorders. The features of the exhibit are equipment recommended by the United States Fuel Administration. In charge of exhibit: S. W. SMITH.

UNION DYE & CHEMICAL CORPORATION. Samples of dyes, showing the dyeings; samples of dyestuff intermediates and heavy chemicals, the latter being raw products for explosives manufacture which are being supplied by the company to several governments.

UNITED FILTERS CORPORATION. Demonstration of a model of the American continuous suction filter: a large type of filter with approximately 65 square feet of filter area will be exhibited to give an idea of the commercial size machine; an intermediate size of the Sweetland type of filter with a cake capacity of 32 cubic feet

of solids; a small model of the Kelly filter; Sweetland patent metallic filter cloth, and a filter lead of the all-metal type. In charge of exhibit: H. J. RUNYON, JR., A. W. SCHMIDT, C. B. OLIVER.

UNITED LEAD COMPANY. "United" lined products, including lead-lined pipes, fittings, valves, centrifugal acid pumps, lead-coated sheets and coils, lead-lined tanks and kettles. The centrifugal acid pumps, lead-coated sheets and some of the valves have been developed since the beginning of the war. In charge of exhibit: C. B. HOLDEN.

UNITED STATES CAST IRON PIPE & FOUNDRY COMPANY. Exhibit of facilities for manufacturing cast-iron pipes and castings used in chemical and allied industries. In charge of exhibit: H. A. HOFFER, C. D. DONALDSON.

U. S. INDUSTRIAL ALCOHOL COMPANY. A display board showing the many uses of alcohol in the arts and industries. Illustration of the company's plants and methods of transporting raw materials and products. An exhibit will be made of the use of alcohol in removal of carbon from cylinders of explosion engines. The products exhibited will comprise ethyl alcohol, cologne spirits, wood alcohol and refined fusel oil. In charge of exhibit: A. H. LESLIE.

UNITED STATES INDUSTRIAL CHEMICAL COMPANY. An exhibit of the company's products, including acetone, methyl acetate, ethyl acetate, amyl acetate, ethyl methyl ketone and light and heavy acetone oils. Photographs illustrating the extent of the manufacturing facilities of the company. In charge of exhibit: E. H. LESLIE.

VALLEY IRON WORKS. Machinery for the chemical and explosive industries, consisting of autoclaves of laboratory and semi-commercial sizes. These machines will be identical in every particular except size with the large commercial apparatus. In charge of exhibit: THOMAS SENIOR, RAYMOND L. RILEY.

WARNER CHEMICAL COMPANY. A full sized model of the Nelson electrolytic cell for the production of chlorine gas and caustic soda. There will also be on exhibit, a flow sheet of the products manufactured by the WARNER CHEMICAL COMPANY and the base materials from which they come. The principal thing of interest on this is acetic anhydride which prior to the war was almost entirely imported from Germany.

WERNER & PFLEIDERER COMPANY, INC. An exhibit of laboratory sizes of "Universal" kneading and mixing machines; a rapid dissolver, laboratory size, hand driven; a new direct motor-driven laboratory grinder. In operation. These machines will be available for tests or experiments which visitors to the exposition may desire to make. In charge of exhibit: EMIL STAEHLE, A. J. VOLLRATH, C. PLETSCHER, EUGENE SCHILLER, J. C. CALEY, S. D. GRIDLEY, J. J. MEGIERIAN.

ZAREMBA COMPANY. Evaporators. Owing to the nature of the apparatus in which this company specializes, it is impossible to make an advantageous exhibit, hence the display feature is eliminated. In charge of booth: H. E. JACOBY.

ZAVON, INC. An exhibit featuring the use of Zavon, the textile solvent, in the textile trade as an aid in bleaching, softening and dyeing. This is an entirely new product since the beginning of the war. In charge of exhibit: T. W. PRITCHARD, CHARLES S. SAWYER.

## Are You a Good American?

EACH good American wants to do his share toward winning the war. If he may not fight or engage in the various forms of war work over there, he wants naturally to have the feeling that he is working for his country here. Through the purchase of Liberty Bonds of the Fourth Liberty Loan, now at hand, the opportunity for just that form of service is given to all.

Whatever the occupation by which one earns his living, it can be turned into war work by way of Liberty Bonds. However indirect its connection with the prosecution of the war may seem, the connection can be made a direct one, if it contributes to the lending of money to the Government. Work produces capital, that is, an accumulation of goods, material riches, results from the daily labor of America. Capital is needed to carry the war to its end. A little taken from the gains of each worker, and set aside for bonds, will make the individual a direct participant in the country's war activities.

No one should miss the opportunity. No loyal citizen, anxious to help defend the United States against the aggression of the enemy, will miss it. Just a little saving, slight self-denial, a cutting off of some of the frills and luxuries of life to which good wages and nation-wide prosperity have accustomed us, will make it possible for every one to lend money to the Government. The widest possible distribution of the Fourth Liberty Loan is desirable on many counts. In the first place, it is the soundest kind of financing to spread securities broadcast. It enlists the active interest of all who buy them for the purpose for which they are issued. Then again, the more people there are who buy these bonds, the more people there are who have thus signified to Germany their intention to work unceasingly for victory. That is the spirit—the national will to win—which even the German people can understand.

If we all buy bonds, we can say to the soldiers who return at the end of the war, "We did our part at home while you were doing yours abroad. Together, we won the war and preserved America."

## Lack of Life in the Rubber Section

THE proceedings of the Rubber Section of the American Chemical Society at its Cleveland meeting were unimportant. Substantially no new information was given out and while problems discussed were of considerable weight, no valuable decisions were reached. The trouble with this section is that most of those who attend its meetings are ready and anxious to

get valuable information but are unwilling to disclose anything of much worth. Many of the gentlemen present could have added to the store of knowledge without difficulty and without real injury to the interests they represented, but they remained silent owing to the medieval attitude of most of the rubber companies.

It does beat all how slow we Americans are to learn that you can't get something for nothing. The business is thriving while rubber is scarce. Every improvement in technique that is introduced is of benefit to the industry at large, and while competitors are expected to compete, they are all in the same boat and they constitute the American rubber industry. There is nothing in the Sherman law to hinder them from co-operation in scientific development, and unless they work together in this respect they are likely to fall behind. The market for crude rubber is open to all civilization and the country that works it up to the best effect will get the trade. Great strides have been made but there is very much to be done still.

It comes to us on the authority of the *Chemical Engineer* of London that Professor Duisberg, of malodorous memory to those who recall the Eighth International Congress of Applied Chemistry, has developed in the Bayer Works in Germany the manufacture of synthetic rubber (methyl rubber) to a present extent of 150 metric tons per month. For several months they have been turning this out and in the meantime they have constructed larger works at Leverkusen with a capacity of 2000 tons annually. The quality is said to be inferior to natural gum but it answers the purpose of helping the Huns. If a similar advance has been made in this country it remains a secret, and we are skeptical enough to believe that it has not been attained.

The Rubber Section of the American Chemical Society needs a good jolt. It should organize itself into a Rubber Institute and get busy. It will not do the industry any harm for the various manufacturers to permit information to be contributed to the common cause; even then they will not know too much. There remains such a vast deal of work to be done that it is unprofitable to sit tight on secrets.

### Jealousy Among the Mighty

**J**EALOUSY is one of the yellowest of human attributes and is not confined to the meek and lowly. On the contrary it aims for the high spots and very often it strikes them. It is the most useful tool of the High Command of the German Foreign Office and for years German agents have been actively fomenting it and encouraging it wherever the voice of the German All-Highest does not sound like the Voice of Divinity.

Some faults we are likely to outgrow as the years press upon us. We are less likely to flare up and shout and make offensive noises in speech than in our salad days. If we find our efforts frustrated, no matter how good the cause may be, we are likely to want to cripple the frustrator or, let us say, the instigator of our whilom inconvenience—when we are all frank and twenty. Speaking conservatively, we are ready to cut his heart out, to tear him limb from limb, to parcel his person for general distribution. With greater maturity we are disposed to address ourselves to overcoming the

difficulties of the task in hand rather than to tear around like a tiger. But jealousy clings on, and there is not one of us, no matter how exalted his position, who is not likely to be touched by it. The colonel of a regiment is rather the natural prey of the passion than the youngest subaltern, and a general is more likely to have occasion for jealousy than a colonel.

It is not many years ago that captains of industry functioned as our minor deities, and the petty jealousies which reigned on the Olympia of Wealth became so widely known that they were recognized along with traditional mothers-in-law, goats, Limburger cheese, tomato cans and other time-honored objects as a source of humor.

But now we are at war and jealousy among the mighty is not funny at all; it is no funnier than treason. Once in a while we come across the evidences of it in high places and it takes more than a little patience to be perfectly good and quiet about it. The only safe thing is to engage in a little earnest meditation every time an important decision is reached. If there is any possibility that jealousy has played a part in reaching a conclusion, the whole subject should be taken up *de novo* in order to banish the poison. If two men are working at the same task and one gets ahead of the other, that is a reasonable cause in these days for congratulation and nothing less, because the work is the sooner completed. We are at war and time is everything. There is not one of us too big to be jealous, and some delays—although far from all of them—can be attributed to no other source.

If we were only conscious of jealousy when it begins to confuse us and make us defective it would not be so dangerous; but as a rule the subject of the trouble is the last one to learn of it. And everybody denies it. On the other hand, there is not a man of responsibility who should not constantly hold himself on guard against it. It is a serious danger. It has frustrated more in the way of achievement than stupidity itself.

### Talking Too Much At the Wrong Time

**T**HE chemical exposition serves the excellent purpose of distributing information among loyal Americans, but we are sometimes disposed to forget that enemy aliens can read, write and cipher. They can also make intelligent observations, and there are thousands of ways to get their information over the lines from Holland, Sweden, Norway and Denmark. Enemy aliens do not wear special uniforms or insignia of any sort, and they do not all speak with a German accent. They are not all herded in concentration camps and they are very active when they are at large.

Chemists engaged in industry are likely to be secretive about their own work. We do not hesitate to criticize this as a fault, more particularly in the short-sighted administrative men who, having the power, forbid them to speak and give out anything but urge them to listen and get something if they can. On the other hand, being pressed and squeezed with secrecy in respect to their own work, they are likely to be gossips about that of others. In fact, scientific men are said to be rather talkative among themselves. This is all as it should be; indeed, we are, ourselves, purveyors of sci-

tific news, and we should be in a bad way if our friends were to lose their curiosity. And we are not charging our friends with indiscretions in speech. We merely know that indiscretions have occurred somewhere, and our present purpose is to caution chemists and engineers as well as to take it to heart ourselves.

We are in the midst of war and the lid is off. It is the nastiest, dirtiest war that ever was fought. There seems to be no bottom to the German's depravity and no portal to his mind save that which may be discovered by his own methods. Therefore with such devices as poison gas in general use, it stands to reason that the only value to some of these outrageous man-killing things is to be there, to paraphrase the late General Forrest, the firstest with the mostest devilment. There is no advantage when both sides employ the same novelties in munitions; the advantage lasts only as long as one side has it and the other has not.

We have been amazed to hear a lot of loose talk going on in regard to what is about to be done, and concerning many inventions in proposed warfare of which the enemy should know nothing. We learned the other day of the almost public congratulations offered to an inventor who had invented an instrument that might be of signal advantage for not over a week, after which the enemy would doubtless prepare himself in a similar manner. The greatest possible secrecy had been observed and yet here was the subject made common gossip, and very likely known at German headquarters by this time.

There is only one thing to do about details of novelties in munitions or chemical or any other kind of warfare that may be under advisement but not yet introduced at the front, and that is to shut up, tight, no matter what we hear. There will be plenty of opportunity to talk about such things after the war.

### Basic Eight-Hour Day in Steel Industry

THE action of the United States Steel Corporation in deciding to establish "the basic eight-hour day" in its plants doubtless means general adoption by the iron and steel industry. An outstanding feature of the decision is that it was reached without any suggestion in that direction by the National War Labor Board. It is related, indeed, that at least a twelvemonth ago there were several operating heads of Steel Corporation subsidiaries who favored the adoption of the basic eight-hour day at that time.

This is a war-time measure in a double sense. On the one hand, it is a long step in the direction of encouraging maximum effort on the part of employees. The workmen will not be disposed to seek shorter hours when they are being paid time and a half for the hours per day in excess of eight, and that means just so much labor kept in the American war machine. On the other hand, the eight-hour day was destined eventually to become quite general in the industry, for the twelve-hour day could not continue indefinitely, and much of the work must perforce be divided into either twelve-hour or eight-hour shifts. If the eight-hour principle were to be adopted at some time, war-time with its attendant dislocations, is a better time than ordinary peace times, when the necessary arrangements would be much more difficult. At some time after the war, perhaps soon,

perhaps far distant, the labor supply will be such as to make feasible or even to dictate, the establishment of eight hours as the day's work, and the change will take the logical form of dispensing with overtime work, with its attendant money bonus. Such a change may still be somewhat difficult, but it will not be as difficult as if the basic eight-hour day principle had not been introduced as a stepping stone.

As the iron and steel industry was organized—or rather unorganized—before the war the introduction of a three-shift system in work where a two-shift system prevails could not have been accomplished with no change in the rate of pay per shift, because an increased wage-cost of 50 per cent would have been involved, and competitive conditions stood as a barrier. The money cost of introducing the basic eight-hour day, on the other hand, is almost insignificant as such matters go now. It means 16½ per cent advance in the day's pay for 12-hour men, and 10 per cent advance for 10-hour men. Some other adjustments may be required for men working less than 12 hours, but the total payroll increase to all employees is not likely to be as much as 10 per cent. In comparison with this, there is the record that during 1916 there were three 10 per cent wage advances in the iron and steel industry, in 1917 two 10 per cent advances, and already this year a 15 per cent advance and a 10 per cent advance, making a total war record of seven wage advances. The eighth is now that involved in the introduction of the basic eight-hour day. The seven advances had approximately doubled wages.

There has been no ground for assuming that after the war the iron and steel industry's wages would either remain at the war-time level or would decline to the pre-war level. Some intermediate ground would be found. In this new alignment the ground will be found at a higher level, in terms of rates per hour, than would otherwise have been the case. The amount of the industry's readjustment, in costs and selling prices, is correspondingly reduced, and that is certainly not disadvantageous.

Within a very considerable number of years, at least, steel will not be nearly as cheap as it was before the war. That will not be altogether an evil. The war has taught men much as to the intrinsic value of materials. Food material, for instance, is on all hands regarded with much more respect than formerly. It is made to go farther, and so with clothing, lumber, practically everything. Steel must be made stronger. If it used to cost 10 per cent of the price to make it 20 per cent stronger it will not cost as much as 10 per cent of the new price, with its higher basis, to make the increase in strength. There was a time when Mesabi ore was mined as cheap as dirt, and transported a thousand miles, by rail, water and rail, for \$2 a ton, other operations being in proportion, and tons of steel were almost no consideration in making a structure strong. In future steel will be made and used more carefully.

These changes enlarge the field of the metallurgist and engineer. There is a fresh demand created upon the metallurgist to improve the quality of steel and upon the engineer to save labor. Jobs that were not the province of labor-saving devices are made so. The production of steel must become still more nearly automatic.

## Readers' Views and Comments

### Synthetic Phenol

*To the Editor of Chemical & Metallurgical Engineering*

*Sir:*—The recent article by Mr. A. G. Peterkin, describing the Dennis Bull synthetic phenol process is very interesting to manufacturers, but the advantages which it is said to offer are open to question.

The value of any process depends largely on the way in which it can be linked with other lines of manufacture to produce or to utilize by-products. It does not usually pay to operate a recovery plant when the by-products can be sold, and where the investment, needed for the recovery plant, could be used for direct manufacture.

The demand for chlorine and its products has kept pace with, and is now even more urgent than that for caustic, and promises at present to continue so indefinitely. The demand for sulphite of soda, and other salts requiring carbonate of soda or its equivalent, is now so great that it would be a mistake to convert it into caustic.

For producing phenol to the best advantage in the United States, a plant should be located where cheap coal and electricity are available, far enough West for a cheap acid and salt, but yet within reach of the market for soda and chlorine products. It would be operated in connection with an electrolytic caustic and chlorine plant, and a contact acid plant able to compete with the zinc by-product. The by-product soda would be used for making sulphite, bisulphite, sulphide, hypsulphite, chlorate, phosphate, or other such salts.

In comparing the processes it should be taken for granted that they are operated with equal skill and all losses, including those due to shipping, storing, and handling should be included in the figures. In the article, the figures given for raw material required are evidently based on the experience in the Barrett plant with the  $\text{CO}_2$  acidification, and do not represent up-to-date practice with the "old" type of process as worked elsewhere.

The excess acid used in the sulphonation should not exceed 60 per cent of the weight of benzol sulphonated, and as there is 10 per cent excess required in the Barrett process, the actual saving is not over 50 per cent. To make this saving requires the handling of 50 times the weight of the sulphonic acid or 200 times this of benzol. As benzol is worth three times the cost of acid, the value of that used in the extraction is 600 times that of the acid to be saved, so a loss in handling of one-sixth of one per cent would offset the saving.

The figures for these losses are not given, but I doubt very much if, when all losses are included, the Barrett process as described can equal the 93 to 95 per cent over all yield now expected in the old process plants.

There is a net material saving shown in acid, lime, soda ash, steam for evaporation, labor, and plant costs, but the salt made contains an excessive amount of sulphate of soda and requires a considerable increase in the caustic needed in the fusion. This again increases

the volume of liquors in the acidification where the most serious losses of the process occur. The process should be modified to remove this impurity by a preliminary separation of the sulphate and the treatment of the resulting mixture of sulphate and sulphonate by the lime and soda process in the usual manner.

When this is done, and all losses figured, this part of the process may still show a saving, especially in a plant where benzol can be had at production cost, but acid and lime must be bought.

For the fusion, the choice of a liquid or dry salt is an old question, and the liquid has been frequently used. Experience shows that yields of over 90 per cent are exceedingly hard to maintain with either a liquid or dry salt, but that 95 per cent, with occasional fusions running 97 to 98 per cent can be obtained with a moist salt in proper condition. With such salt the capacity of drum dryers is very great, and the steam and labor required to run them is more than offset by the saving in time, and fuel in the fusion. The water must be evaporated somewhere, and it should be done where it is cheapest, and does not interfere with other work.

While the acidification by  $\text{CO}_2$  presents no great difficulty to the experienced man, it has given a great deal of trouble in some plants where it has been tried and requires more skill than either acidification with sulphuric acid or  $\text{SO}_2$ , and should not be considered for either a war-time plant or a permanent one, as the  $\text{SO}_2$  obtained from the neutralization of the sulphonic acid with sodium sulphite supplies a large part of the acid required, and a sulphur burner worth a few hundred dollars can furnish all additional gas for a large plant. Of course, in an acid plant, gas from the ore burners is available. The sulphite produced by this is worth more than the caustic and there is a large increase in the weight.

One of the most serious difficulties of the acid and the  $\text{CO}_2$  acidification is the tendency to form emulsions, if too concentrated solutions are used. To avoid trouble, the workmen dilute them to excess. Phenol is very soluble in a solution of phenate or of undecomposed salt, and as the bulk of the liquors is great, a small percentage of phenol in the liquor will represent 10 to 20 per cent of the total phenol. The statement is made that the liquor can be completely freed of phenol and a 4 per cent distillate obtained by distilling with steam. Experiment shows that the vaporization of phenol is a function of concentration and that there would still be phenol left, when the distillate showed 2 per cent, from a liquor containing 2 per cent, which would require the evaporation and condensation of about twenty tons of water per ton of phenol made.

Probably the best method of acidification is to use  $\text{SO}_2$  only, and separate the sulphite as formed. The wet sulphite is saturated with  $\text{SO}_2$  to complete the decomposition of any phenate, and then dried below  $150^\circ\text{C}$ . in a current of steam. Still residues and any sludge formed go in with the sulphite, and the phenol is re-

covered with practically no loss. The distillate and fore-run are used in the quenchers, with the liquor from previous batches. As no water is added except as steam, and there is considerable evaporation in the quenchers, there is no liquor to dispose of, and the sulphite is free from phenol, and in excellent condition for any other use. Owing to the comparatively small amount of water to be evaporated, the cost of the drying is small and it prevents accidental losses such as occur with liquors.

In the matter of labor, any difference would be more in the design of the plant than the process. Labor in most phenol plants at present is higher than it should be, because they were designed by men who did not yet know the essentials of the process and modern methods, and changes in an old plant are hard to make satisfactorily.

In regard to transportation, any statement which includes a movement of raw materials, but falls short of a complete analysis of movements of by-products, is apt to be misleading. In any case it depends on the location of the plant and the average distance of the market.

E. E. HOTSON.

## An Outgo, Not an Income Tax

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—The proposed new sumptuary tax bill before the Ways and Means Committee of the House of Representatives comprehends raising eight billion dollars annually by taxes on clothing of the more expensive grades; on jewelry, automobiles—in fact all luxuries and many necessities. If one of us pays more than \$2.50 for a hotel room, the state will impose a heavy tax, and so on. This tax is a tax on excess expenditure and is planned to inhibit all luxuries and to reduce to a minimum any waste of essentials. By its enforced economies it will go far towards paying the bill for the war, and in its nature, we think is to be preferred to any great increase in the income tax. For is not an outgo tax, stopping foolish consumption, better than an income tax which puts the brakes on production? The state should desire to stimulate incomes and to stop foolish outgo.

This new departure in taxation coming as it does after other new departures suggests the saying rife among sociologists some six years ago that "socialism not on Marxian lines but socialism by taxation is here." We doubt much if the policy of Government socialism by taxation endorsed and sponsored by the Democrats, the party of Jeffersonian simplicity and individualism, will become less marked in the decade following the end of the war, and we believe that the policy of taxing excess expenditures will be in vogue for years. As a tax on outgo rather than on income it stimulates a healthy growth of trade and industry and tends to conserve and stabilize wealth rather than to destroy and scatter it.

Now, these premises and propositions elucidate further the obvious fact that the country where justice, freedom and intelligence rule, will, after the war, be the best country to live in, for the Bolsheviks are not a cause but a result of graft, license and ignorance. Therefore, if the United States is to grow and flourish, if it is to retain its position as a refuge for the oppressed, retaining a capitalistic form of government and the rights

of property with this new Socialism by Taxation, it must have an intelligent government and an intelligent system of taxation. When this is attained capital and labor will harmonize and we can be exceedingly prosperous because of our industrial and psychological security and stability, and we can afford to pay large taxes.

Now this second set of premises and propositions suggests a further line of thought. If taxes be high, interest rates of course will be high, interest being the measure of the productivity of capital. If interest rates be high, capital must be fruitful and there is no better way for capital to fructify than in the chemical and metallurgical industry. Offhand, we can recall a metallurgical plant costing \$6,500 that with \$50,000 working capital made a profit of \$1,000 per day, and another costing \$175,000 that made \$750,000 per annum. While these are startling exceptions, they only prove the rule that by intelligently directed scientific work capital can be made most productive in the chemical and metallurgical industry. Since it does not seem entirely fanciful to believe that after the war the normal rate of interest may be as high as one per cent a month—the actual legal rate at Rome for centuries, when that great empire flourished under the *Pax Romana*—we incline to the opinion that the future high rates of interest will force an enormous growth of applied chemistry. Granting a well and intelligently managed system of government that induces a feeling of peace and security, capital will increase correspondingly fast. And one sign of intelligence in government is a tax on outgo, not on income, such as now emanates from Washington.

"CHEMIST."

## Research Preparedness in the Zinc Industry

*To the Editor of Chemical & Metallurgical Engineering.*

SIR:—The letter of Mr. Eric John Ericson in your issue of August 15, takes issue as to my attitude towards the value of the sulphuric acid industry as a corollary to spelter manufacture.

My attitude is that while the acid corollary may show on paper in normal times a value of a dollar or two a ton of zinc ore, and does in war times show a value perhaps exceeding \$5 per ton, the manufacture is attended with increasing costs of roasting due to the type of fine burners necessary and the character of flotation slimes used as feed, yielding an abnormal degree of dust in flues and chambers. This coupled with fuel and labor costs is perhaps going to change the balance-sheet after the war.

Again I felt that the freight upon the acid to market was a serious item and often decided the location of a zinc smelter and this involved freights on zinc ore.

I spoke in very broad terms, looking ahead and realizing that the zinc industry was about to see radical changes in metallurgical and economic practice. While zinc distillation in modernized form will still continue to be practised near population centres, and thus have a sale for acid, the reason for such location will be because of the market for domestic briquet fuel which will constitute the most valuable corollary in connection with zinc distillation, because it alone will reduce the fuel costs to the lowest figure, which condition will be necessary to meet the coming heavy competition of cheap water power and cheap zinc by-product concentrates in the northwest.

PARKER C. CHOATE.

## Western Chemical and Metallurgical Field

### Great Falls Rod Mill Commences Operations

A NOTEWORTHY event in the progress of Western metal manufacturing occurred early in June, when the new rod mill of the Anaconda Copper Mining Company started operations. This mill is erected at the Great Falls plant on the high ground north-east of the big stack, and is designed for a capacity of 100 tons of copper rods per shift of eight hours. When operating three shifts, the plant may reasonably be expected to maintain a production of 250 tons of finished material daily. At present only one shift is in operation, its output being rods about 0.4 inch in diameter, which are being reeled and stored awaiting completion of the die benches. Partial operation was thus inaugurated six weeks before expectations; complete operations will be instituted within a very short time.

The mill is equipped with a Rockwell heating furnace designed for oil- or coal-firing. The roughing rolls take the regular 4-inch wire bar through nine passes, delivering to a stand of intermediate rolls next in train. At the present time three passes through these intermediate rolls are used to reduce the rod to 0.4 inch. Finishing rolls directly alongside will make sizes from this down to about  $\frac{1}{4}$  inch.

Other equipment about ready for operation consists of a 4-die machine for special sizes and shapes, a 4-die machine for trolley wire, two 10-die machines for small wires, and four stranding machines for making cables, together with the necessary auxiliaries such as pickling tubs, bright-annealing furnace, and brazing furnace. It is expected that the plant will produce a good proportion of the trolley wire and bonds required for present and future western railway electrifications, together with important quantities of copper products for the general electrical and jobbing houses that are located in this region.

### Potash in 1917

THE United States production of potash bearing materials during 1917 is reported in a recent statement from the United States Geological Survey. Three times as much was reported as in the preceding year—it amounted to 126,577 tons of material, containing an average of 26.4 per cent  $K_2O$ , representing 32,366 tons of pure potash, which is practically the amount predicted at the middle of the year by Hoyt S. Gale of the Survey. The average selling price at the points of production was \$4.26 per unit—that is to say, 21.3 cents per pound of  $K_2O$ —making the value of the potash produced during 1917 equal to \$13,791,922. The quantity produced is about 13 per cent of the normal consumption of the country prior to the war, and while it is far from adequate, still the most insistent demands can now be met.

The Nebraska lakes produced nearly half of the entire output, shipping in the neighborhood of 14,500 tons of pure potash. However, this is hardly half the potential production of the plants operating in that field at the end of the year. The discrepancy is an indication of the rapid expansion of the industry. Much of the capacity was not ready for operation before the year was nearly gone. It is a further indication of the

extreme difficulty in the labor, fuel, and equipment supply and the transportation situation.

The potash produced from kelp represents about ten per cent of the total. A large part of this was high-grade potassium chloride, and the balance was kelp char containing 16 to 36 per cent of water-soluble potash. An unexpected shortage on the kelp crop curtailed the production from this source.

The production from alunite was disappointing, but bids fair to be largely augmented in 1918. This is also true for potash from cement plants. In the latter case, eight mills reported a production of 13,582 tons of dust containing 1621 tons of  $K_2O$ . Installations for the recovery of this fertilizing material as a byproduct of cement kilns are going in apace, and it is expected that the output for the current year will be second only to the production from brines. Such plants are particularly desirable, since they recover the material at such a slight cost that they can continue in operation when the selling price of the material has dropped to a very low level.

Minor amounts of potash were recovered from the residue of charred molasses wasted from alcohol distilleries, the waste liquors from beet-sugar manufacturing, and from the stoves and dust catchers at iron blast furnaces. Crude potash is still produced by a number of small operators by the old methods of leaching hardwood ashes. Thirty-six producers, chiefly in Wisconsin and Michigan marketed about 700 tons of material, estimated to contain about 424 tons of  $K_2O$ . Wool washings and organic wastes from several other manufacturing plants also added their quota to the total.

**The Portland Gold Mining Company.**—The Independence Mill was completed about the middle of the past year, being considerably delayed by slow deliveries, at a cost considerably greater than originally estimated. It has been operated continuously since completion and is gradually approaching the expected capacity of 42,000 tons per month. The cost of treating low grade ore at this mill at prices current eighteen months ago, would be materially less than expected when the mill was designed, and consequently it will form a very profitable asset to the company on the return of normal price levels. During the past year 592,995 tons of crude ore and waste were mined and handled. After sorting, this yielded 75,542 tons of shipping ore sent to Colorado Springs, which gave a gross return of \$1,617,406.62 or \$21.40 per ton. The Victor mill handled reject, mill dirt from stopes and development work, and dump ore totalling 236,915 tons, with average values of \$1.762. The Independence mill handled reject and dump ore totalling 236,915 tons, with average values of \$1.762. The net cost of mining and milling amounted to \$1,864,265.61, and the net profits of the company for the past year, as far as mining and milling operations are concerned, were \$666,254.42 (\$768,809.84 in 1916). The mine manager, Mr. F. L. SMALE, makes some interesting observations on the labor situation in the district, as follows: "Early in the year the effects of the war were noticeable in the labor situation, our best miners quietly leaving the district and going to other camps where special inducements were offered for skilled men. This condition has continued, notwithstanding a wage increase that was asked for and granted."

## Cleveland Meeting of the American Chemical Society

**Important Actions by the Council—Large Attendance at Technical Sessions—Successful Symposia on Dyestuffs and Potash—Social Features**

THE annual meeting of the American Chemical Society was held at Cleveland on Sept. 9 to 13. The attendance was larger than was expected, the registration list showing nearly 600 members. At 4 p.m. the Council met at the University Club. In the absence of the president, DR. W. H. NICHOLS, who was detained at home by an injury to his knee, the senior vice-president, DR. H. S. MINER, presided. The several vice-presidents are also respectively chairmen of the various divisions and their rank accords with their seniority as members of the society.

### COUNCIL MEETING

It was reported that the chemical census which is being prepared in cooperation with the Bureau of Foreign and Domestic Commerce will be ready for the printer about December 1 and that it should be ready for distribution about February 1, 1919, at the price of 30c. per copy. Further details regarding this census and other statistics on the chemical industry have already been published<sup>1</sup>.

The editors of the various journals were re-elected as were also the retiring members of advisory committees. In the evening the Council were guests of the University Club at dinner.

### PROMINENT GERMAN CHEMISTS DROPPED FROM ROLL

On Tuesday morning the general meeting was called to order by Vice-President MINER at Hotel Statler at 10 a.m. There was presented from the Council the following preamble and resolution which were unanimously adopted:

WHEREAS the behavior in war of the German people has dishonored them among the enlightened nations of the earth and proved them unfit to associate with civilized men and women, and

WHEREAS Walther Nernst, Wilhelm Ostwald and Emil Fischer have been actively associated with the German Government and its people in their conduct and offenses, now therefore be it

RESOLVED that the said Nernst, Ostwald and Fischer be dropped from the rolls as honorary members of the American Chemical Society and that this act be construed to take effect as of August 1, 1914.

### THE CHEMISTS' PLACE IN WARFARE

Professor A. W. SMITH of the Case School of Applied Science made an address of welcome, which was responded to by Vice-President Miner. The Secretary, DR. CHARLES L. PARSONS, read a paper on The American Chemists' Place in Warfare. He related that toward the end of 1916 he made a trip on behalf of the United States Government to England, France and Italy and that in all these countries complaints were persistent of their loss of chemists and technically trained men, and

that at the time of his visit each of these countries had withdrawn her chemists from the line.

In order to provide as far as possible against scientific and technical inadequacy in this country, the American Chemical Society, through its President Dr. Julius Stieglitz, offered the services and facilities of the Society to the President of the United States, shortly after war was declared. Following this, the Bureau of Mines in cooperation with the Society, prepared a census of the chemists of the country, beginning in February 1917. Over 17,000 chemists have sent their records, qualifications, age, etc., to Secretary Parsons in reply. Additions are being constantly made to this list. Over 50,000 circular letters and 10,000 personal letters have been forwarded from Washington in the correspondence which the census entailed.

The intensity of the need for chemists was noted as soon as the war began and this increases as time goes on. Over 700 with 1100 helpers are engaged in Washington in one government laboratory on gas work alone, and branch laboratories have been established at Johns Hopkins, Harvard, Yale, the Catholic University of Washington, Bryn Mawr, many state universities and in a considerable number of manufacturing establishments. In June 1919 the work was transferred to the War Department. In the meantime the medical, ordnance and other departments have called for more chemists, and the number has been materially increased. The staff is now so organized that assignments are made as needed. The authorized personnel of the Chemical Warfare Service is 45,000 of which a much smaller number are chemists.

Mr. CHARLES H. McDOWELL read a paper on The Work in the Chemical Section of the War Industries Board. He said that the main difficulty with the United States was that it had been called upon to start big business at the top. This had often entailed loss and expense which only time could have avoided; and there was no time. It is evident, he held, that if the war continues much longer the production of certain materials for the open market must be curtailed, which calls for sacrifices from industries as well as of materials. The unanimity with which leaders of industry have met the demands of war, without complaint and in entire willingness calls for the greatest praise. The Board has 18 sections, and representatives of these meet every morning with the chiefs of buying commissions for the Allies as well as with representatives of the U. S. War and Navy departments to consider what it wanted and where and how it may be obtained. The Board itself does no direct buying but it fixes prices to be paid for staple products.

Certain parts of the country are now over-burdened with war contracts. For instance the district between Altoona, Pa., and Norfolk, Va., is now at its maximum economic capacity and no new contracts or new in-

<sup>1</sup>This journal, Sept. 24, 1918.

stalations can be encouraged in this district. The steel situation, said Mr. McDowell, is desperate. There is practically no structural steel that can be produced. Even Government buildings must be erected without it. Dr. Weidlein, acting director of the Mellon Institute and Dr. Moody of the College of The City of New York are among the Board's consultants and the research facilities of the Mellon Institute of Pittsburgh have been placed at its disposal.

DR. GRINNELL JONES, chemist of the Tariff Commission delivered an address on War Disturbances and Peace Readjustments in the Chemical Industries<sup>2</sup>. He said the greatest changes have been wrought in the chemical and metal working industries, and that the Tariff Commission is actively engaged in studying the situations.

#### CHEMISTRY AND SHIPPING

Ships are no longer permitted to seek the most profitable cargoes. The War Board determines what may be brought in and what may not. The advisory chemist on the staff of the War Board is DR. PENNIMAN of Baltimore. An example of something supposed to be needed but finally prohibited is tapioca. Aside from the familiar pudding it was needed for its starch to make gum for postage stamps and nitro-starch, which is now one of the safest explosives. The Post Office Department soon discovered a substitute and after rapid but intensive research, it was found that nitro-starch may be made from cornstarch—which theretofore was utterly impossible—and that the resultant product is better in quality and cheaper to make than from tapioca starch. And the avoidance of importing tapioca provides shipping to carry over and to supply 25,000 men.

There is a great diversion of materials from their normal use into war needs. Thus the fertilizer industry suffers not only from lack of potash, but from nitric and sulphuric acids and ammonia as well. Peace conditions should make great changes in fertilizer production. And he emphasized the fact that the *status quo ante* cannot be re-established in chemical industry.

#### GAS WARFARE RESEARCH

LIEUT.-COL. WILDER D. BANCROFT of the Chemical Warfare Service spoke on "Chemical Warfare Research." It had to do with the great research laboratory for gas service which was established one and a half years ago by the Bureau of Mines and taken over by the War Department on July 1 last. He gave an outline of the general procedure in regard to any given war gas. If a gas is offered as something new it must have certain qualities to receive thorough attention. The substance may be gaseous, liquid or solid, but it must be poisonous, or produce tears to excess or cause nausea or sneezing or it may produce a nose-twisting stench or it may be a smoke with obscuring power. It must be "good" of its class. One milligram per liter must kill a dog in 30 minutes, and if it is a lachrymatory substance it must be effective in dilutions of one one-hundredth of a milligram per liter. The raw material to make it must be available and easy to produce. There should be already established a good method of manufacture, but if the product itself has sufficient merit of wickedness, it is taken up and manufactured even if the only available method be wasteful. It all depends upon

how useful it may be. It must also be fairly stable. The Allies can use material within one to two months after a shell is loaded but our limits against polymerization are of necessity more rigid than those of the British, French or Italians.

The method of procedure, whether the gas be used by the Germans or developed by the Allies or only suggested and considered, is the same. The first step is for the Offense Division to make it. If it is solid it goes to the Dispersoid Division—and we cannot resist a note in appreciation of Professor Bancroft's happy invention of the name of this division. What the Dispersoid Division does with a solid poison gas is explained in true chemical fashion. Then it goes to the Toxicological Section where its degree of toxicity is determined and other properties are observed and recorded. If these reports are favorable it goes back to the Offense Research Laboratory where the best method of production is worked out and then to the Chemical Production Section where it is made in lots of from 50 lb. to one ton. At this point large-scale production may begin either by the Government or it may be assigned to some manufacturer for quantity production.

#### GASES STUDIED BY MANY SECTIONS

In the meantime samples of it have been making the rounds of other laboratories. The Analytical Section (which may have been the first to investigate it if it is a German product) determines the purity and the amounts of it contained in air under given conditions and here also tests are made of its behavior with other materials in canisters. The Pyrotechnic Section determines its stability when fired in shells and the Defense Research Section determines whether new substances must be put into the canisters with it and if so, what they are. It also takes up methods of detection and it may have to develop protective ointments to be used against blisters, etc., which it may cause. The Mechanical Research Section discovers if, with the change in the ingredients of the canister, the type of the canister must be changed. In the laboratory of the Pharmacological Section the general symptoms of its effects are studied and the problem of susceptibility is investigated. It is also the somewhat delicate business of this section to keep especially susceptible men out of the factories in which it is made. The Pathological Section studies in detail the manner in which various organs are attacked by it, while in the Therapeutic Section the task is undertaken to find effective methods of treating gassed men.

Every section reports twice a month, and a vast amount of reports is piling up. These reports go immediately to the Editorial Section in charge of Col. Bancroft. Here they are condensed and incorporated into semi-monthly reports which go to a selected list of persons in America and abroad. Monographs are in process on each subject which contains everything that is known about it, not only from the results of study here but also from the literature and from contributions made from abroad, as well as from captured German reports.

The whole system of the laboratories at the American University, as it is called, is described as very flexible so that each member of the staff may function wherever he is most urgently needed.

<sup>2</sup>Published in this journal, Sept. 24, 1918

## UNIVERSITIES AND CHEMICAL WAR WORK

PROFESSOR EDWARD W. WASHBURN, professor of ceramic chemistry at University of Illinois, but now of the National Research Council, read a paper on The Place of the University in Chemical War Work. He said the U. S. Government will need a great many chemists beyond those now employed and in excess of the normal output of colleges. The source of additional supply is expected to be the Student Army Training Corps. For this purpose the Government will undertake to train recruits of 18 years of age in three grades for the purpose. The method offers the most remarkable opportunity to any young man eligible for war service who is 18 years old and has passed his high school examinations. He may undertake any one of three courses in chemistry, i.e., the one-year, two-year or three-year course. He may go to any one of a number of colleges and study for four terms of 12 weeks each during one year. This will fit him to do routine analysis, and to be a laboratory assistant. The two-year course is designed to fit him for general chemical work in analysis, food, sanitary and technical work and to include the usual courses in chemical engineering. The three-year course is designed to prepare him for research. The study is very intensive and does not include the cultural studies outside of what the student may glean from science and mathematics, and some English in the three-year course. Every twelve weeks he must pass all examinations and no provision is made for failure. Nothing can be made up. If he fails to pass he is transferred to a cantonment for drill in whatever arm of the service men are needed. He receives \$30 a month pay and clothes, board and lodging. The fact is that more chemists are needed than are available and this has been decided upon as the best means for providing them.

The great need is for research. Much is done according to the best means at hand, and a great deal goes on merely because present methods will work. But many of them are far from the best possible methods. A large number are well worthy of scientific study and Dr. Washburn urged upon professors to undertake such problems in their laboratories where the high pressure of the government organizations does not prevail and to set aside their more favorite problems in research for the nonce. There is much to be done in the measurement of physical properties and the study of the chemical nature of materials that cannot be provided otherwise.

An interesting note is also that the U. S. Government now has scientific attachés assigned to the embassies of London, Paris and Rome. Professor Bumstead (physics) of Yale is attached to the embassy at London with a chemist in his staff. Professor W. F. Durand of Leland Stanford University is in Paris while Dr. H. S. Washington, Chemist of the Geological Survey is in Rome with Dr. Edgar Buckingham, a physicist, as his associate. The rank of scientific attachés is similar to those of the army and navy. They are appointed for the collection and distribution of scientific information in international relations. Their dispatches, like others, go by couriers.

## DYESTUFF SYMPOSIUM

At 2 p.m. on Wednesday Sept. 10 the symposium on the chemistry of dyestuffs was held at Hotel Statler.

MR. R. NORRIS SHREVE of the Calco Chemical Co. presided, and in his introductory remarks he made an earnest plea for the prosecution of research. In no phase of applied chemistry are so many by-products developed as in the dye industry and these cannot be neglected. Uses must be found for them and the research laboratory is the only means of discovery. Another point was that American manufacturers have been trained to produce in bulk and to ignore those things which are only needed in small quantity. The function of those engaged in the industry is to supply needs as well as to earn dividends and while the profits on unusually demanded dyes may be negligible, the demand must be met either here or in Germany. Mr. Shreve proposed that the several organizations make each one a number of such products so that there may be the least duplication of effort in unprofitable enterprises and also that the greatest number of such materials be produced.

He urged upon manufacturers to look ahead as far as they can and declared that success would only abide with those who did so. He also emphasized the need of what we have been preaching for years, which is that in the body of final authority over a manufacturing establishment, whether it be its board of directors or its executive committee, there be found at least one member who has chemical understanding and training.

He concluded by announcing that the programs of a number of American dye manufacturers were considerably set aside in order to enable them to make munitions of war.

## AMERICAN PROGRESS IN DYE MANUFACTURE

DR. L. J. MATOS of the National Aniline and Chemical Co. then spoke on America's Progress in Dyestuff Manufacture. He gave the following dates of the discovery of various coal-tar colors which succeeded the discovery of mauve by Perkin in 1856. Magenta was discovered in 1858; aniline black, 1862; nicholson blue, 1862; alizarine (by Perkin) in 1868; cachou de Laval, which was the first sulphur color, in 1873; methylene blue, 1877; azo reds, 1878; propiolic acid, from which followed synthetic indigo after many years, 1880; tartarazine, 1885; primuline, 1887; rhodamine, 1893; and sulphur black in 1895.

Until the outbreak of the war American dyes were at peace with the world, but when German colors were no longer available the troubles came. Makers had to get along with derivatives of benzene and naphthalene because toluene went into munitions and was worth upward of \$10 a gallon. And intermediates had been mostly imported from Germany. What was lacking to make them was the technical training and experience. The problems had to be attacked *de novo* and results, and at first yields, were seldom alike or satisfactory. Materials which had been bought in Germany 99.8 per cent pure were bought here which were 24 per cent, 33 per cent, 28 per cent and 50 per cent pure in successive shipments, the analysis of the last mentioned invoice reading "50 per cent H Acid and 50 per cent secondary products." So that some of the early dyes were off strength and off shade, and what secondary products were, no one could tell, because they were seldom twice alike. In taking up German patents very little enlightenment is discovered, because if, for instance, the product at a certain stage is one which it is practically

impossible to filter, the inventor's description in the patent is likely to read "I then filter"—and nothing more on the subject.

In the meantime great progress has been made. The yields have been brought up to good practice and impurities have been removed so that today there is no inferiority in American-made dyes. In strength and brilliancy of shade, they are, type for type, as good as those which were formerly imported. The company with which Dr. Matos is connected makes 69 different products. The general public is still debarred from the use of toluene which holds back the production of certain colors that are fast to light. These will come as soon as toluene may be used for this purpose instead of for TNT.

Of the 175 dyes now made in America, all are made from American raw materials and these include nearly all the types in use before the war. Among other dyes alizarine (Turkey red) is now produced in quantity sufficient to meet American requirement, and the speaker expressed the belief that the industry would be a permanent one.

#### THE TARIFF AND THE DYE INDUSTRY

DR. GRINNELL JONES, chemist of the U. S. Tariff Commission read a paper on The Production of American Dyes and Coal Tar Chemicals during 1917. The present tariff law on dyestuffs is short but it is none the less complex. It provides a duty of 15 per cent on intermediates and 30 per cent on dyes with a specific duty of 2½ cents per pound on intermediates and 5 cents per pound on dyes. Alizarine and indigo and certain allied materials are excepted from the specific duties. In regard to all other colors and intermediates there is a peculiar stipulation to the effect that after five years the duty on these shall decrease at the rate of 20 per cent per year provided the American production of dyes at that time is 60 per cent of those used in the country. If the country produces less than 60 per cent, the specific duty shall forthwith cease entirely. The critical date is in September 1921 so that it falls upon the Tariff Commission to have this information available at that time. To prepare for it they have reports from 190 manufacturers of whom 12 do not want their names published, chiefly on the ground that they make only for themselves or that they are about to discontinue and do not want to be bothered with inquiries. The Commission is preparing a pamphlet which will contain 178 names and the record of 12 anonymous manufacturers. The Geological Survey has taken the reports of the tar distillers and coke ovens and the pamphlet will also contain the output of crudes of the distillers and stripping plants. The total but not the individual production of materials will be given, except that in cases where the record of the total production would indicate the output of any single manufacturer, they will be omitted. There are 118 firms reporting on 134 different intermediates. The pamphlet will show 5,900,000 lb. beta naphthol and 10,000,000 lb. H-acid made in 1917; hardly any anthracene; the colors will prove to be mostly of the azo group and sulphur blacks, and 300,000 lb. indigo by one maker who was willing to have the figure printed. There were 260,000 lb. of photographic chemicals made. Of synthetic drugs there were made 900,000 lb. acetanilid U. S. P., and 500,000

lb. acetyl salicylic acid. Exclusive of clerks, sales force and others not engaged in manufacture there are 19,643 employees in dyestuff and allied industries of whom 1733 are chemists. The ratio of 8.8 per cent technically trained men is very high for any American industry.

#### DEVELOPMENTS SINCE 1914

DR. J. F. SCHOELLKOPF JR. of the War Industries Board was detained in Washington by official duties but his paper on The Development of the Dyestuff Industry since 1914 was read by Mr. Willard Watkins of the Schoellkopf branch of the National Aniline and Chemical Company. He believes that the problems to be met after the war will be far greater than during the war. The total production in the United States before the war was less than 6,000,000 lb. per year and owing to the nature of German competition the trade conditions were very bad indeed. The business had had a hard experience. When the war began most makers thought it would not last very long and they erected temporary buildings to produce the things that were most needed. These had to be replaced as plans were changed. In the Schoellkopf Works before 1914 they were making some 16 out of the 300 and odd colors in largest use. By January 1, 1916, they were making 40. By 1917 the ordinary needs of industry were beginning to be met with some satisfaction and during that year they produced 46,000,000 lb. of color at a value of \$57,000,000 against \$2,000,000 worth in 1914. Advance would have been impossible without the splendid responses from chemists, engineers and mechanics as well as from foundries and machine shops. Some original research is now under way in the laboratories but the main efforts have been in relation to improvement of quality. This has been so successful that very few colors now fall short of the best German products. Ninety per cent of the complaints today are due to the faulty application of dyes. The dictators of fashion call for shades which involve the use of a mixture of dyes of which some one or two may not be made as yet. Then substitutions of dyes that are not proper for the purpose are made—and trouble follows. Among the best colors he was glad to say that alizarine and fast cotton vat dyes will soon be forthcoming.

He expressed the belief that unless higher duties are placed upon these materials the industry will be seriously jeopardized after the war. On the other hand, if the industry were to receive the protection of high duties for ten years he believed it could thereafter get along without any protection at all.

#### PROGRESS IN APPLYING NATURAL DYES

DR. EDWARD S. CHAPIN of Boston spoke on An Important Factor in Natural Dyestuff. His paper was a scholarly presentation of the chemical structure of the tinctorial bodies of natural dyes, reviewing the studies of Professor Perkin and others. He brought out arguments in favor of certain natural dyes and declared that logwood, if properly dyed upon wool is fast against light and that it will not crock. Dyers preferred coal-tar colors, he said, because they are so much easier to apply. Research is under way and the outlook is promising that certain natural dyes may be so treated as to make them as easy to apply as the synthetic colors.

DR. J. MERRITT MATTHEWS spoke On the Application

of Dyestuffs in Cotton Dyeing. The special nature of cotton and its requirements in this respect were pointed out.

MR. ELLWOOD HENDRICK told of the beginning of the coal-tar dye industry in this country at Albany, N. Y., and of his connection with it as chemical director in 1881-4.

MR. CHARLES R. DELANEY of Hanover, Pa., in discussing the Manufacture, Use and Newer Development of Dyewood Extracts, told with almost aggressive modesty how quiet and unassuming the makers of dyewood extracts had been while all the country had been talking about coal-tar dyes. Nevertheless he declared that they were growing fast; he agreed with Dr. Chapin about the supremacy of logwood on wool in reference to its bloom and richness, and claimed that dyewood extracts were the natural and best colors for silk, wool, leather and wall paper. He said that before the war his firm had shipped large quantities of Flavine to Germany and Switzerland for wall paper. They had sold hardly any in America because they had preferred to save their self-respect rather than complete in the market with German manufacturers. There is, he said, roughly speaking, \$50,000,000 invested in the dyewood industry in this country today.

#### COLOR LABORATORY OF THE BUREAU OF CHEMISTRY

DR. H. D. GIBBS of the Bureau of Chemistry, Washington, described The Color Laboratory of the Bureau of Chemistry. It is not yet finished and part of what is already constructed has been turned over for war work. But when completed it will be a building 150 x 70 containing 9 laboratories, power and refrigeration plants, nitrators, sulphonators, etc. in short a complete small factory. The plans are very ambitious, being no less than the studies of processes and their details for making dyes for the benefit of the general welfare. Although 80 per cent of the staff and of the work is now on war problems, the following is the plan, and, so far as they have gone, the method:

It is aimed to study dye intermediates, dyes, dye methods and medicines. Work has already been done in chlorination, sulphonation and oxidation. Chlorination is effected by means of light catalysts and the studies of sulphonation and oxidation are also made in the vapor phase. As soon as the work in hand is sufficiently advanced separate pamphlets will be published. Such a pamphlet will shortly appear on H-acid. Another study is on the production of phthalic anhydride by oxidation of naphthalene in the vapor phase. A very interesting work is on cymene, recovered as waste from the sulphite pulp industry. The successful nitration of cymene has already been accomplished and the record published in the *Journal of Industrial and Engineering Chemistry*. From this the development of a large series of derivatives is opened up and as many are indicated as there are of aniline. It is especially promising in the field of dyes of which some have been produced already. What part these new dyes will play in industry is an open question but the outlook is promising. Some 2,000,000 gallons of cymene are available annually from the production of spruce pulp. Further studies have been made on the purification of anthracene pressed cake.

The influence of a government laboratory working

over the problems and publishing its findings is likely to be of marked effect. It emphasizes the fact that development along this line is of general public interest rather than an industrial speculation. And although the speaker did not dwell upon the subject, it appears to us as though it would discourage secrecy in industry, and it is usually a good thing to discourage secrecy. In our opinion it is a sign of bad conditions for industry to manufacture in secret and to sell with a brass band. This puts the emphasis upon selling and discourages attention to the art of producing.

#### PROBLEMS IN TESTING DYES AND INTERMEDIATES

DR. E. W. PIERCE of New York spoke on Problems in Testing Dyes and Intermediates. He said the human eye cannot detect a difference of less than 5 per cent in shades although by colorimetric methods this may be brought down to 2 per cent. He laid stress on differences produced by differences in water and said that adulterants such as dextrine often act as protective colloids and slow down the process. He held that we must regard the process of dyeing as one of adsorption and we should bear in mind that we are at all times dealing with problems of colloid chemistry in the dye bath. Referring again to the effect of impurities he recalled the use of synthetic indigotine when it was introduced. The natural product worked well in a large dyehouse under his observation, but the synthetic product, which was pure, gave all sorts of trouble. The goods were uneven and streaky. The fact was it dyed too rapidly, lacking the usual organic impurities which served as protective colloids and thus slowed down the process. The addition of certain organic matter to the bath overcame the difficulty and enabled the dyers to use the synthetic as well as the natural product.

He called attention to the fact that wool differs at the roots from the tops, and that two lots of wool that look very much alike may dye if treated separately, nearly alike but that if dyed together, one lot may rob the other of its color so that part will come out dark and part very light. These differences, he suggested, may be due to the presence of bleached shoddy.

#### QUANTITATIVE VS. ANALYSIS OF DYESTUFFS

MR. ALFRED H. HOLLAND of the Buffalo Works of the National Aniline & Chemical Co. presented a paper on Quantitative Analysis of Dyestuffs which he had worked out in connection with Mr. Willard Watkins in their laboratory. He said there was very little literature on the subject, but that they had found the work of great value in the work in that it enabled them to determine yields. He gave a number of methods. He took issue with Dr. Pierce as to the colloidal nature of dyestuffs; said that the processes seemed usually to proceed as Dr. Pierce described but he knew for a fact that naphthol yellow, for instance, contained crystal water and that indigo, on standing in solution, shifts from a colloid to a crystalline state. No dispute followed, for Dr. Pierce admitted everything and held to his point.

#### DIVISION OF INDUSTRIAL CHEMISTS AND CHEMICAL ENGINEERS

The dyestuff symposium which was attended by upward of 250 persons was continued in the main ball room of the hotel on Wednesday morning, and on the

conclusion of Mr. Holland's paper and discussion the above division convened with Mr. H. S. MINER presiding.

#### SUGAR AND CITRIC ACID

The first paper was by Dr. W. D. HORNE of Yonkers, N. Y., on Valuation of Raw Sugars. He proposed an amplification of the polarization methods in vogue. Raw sugars often contain impurities that remain in the sugars after filtration and thus augment the cost of refining in remarkable measure. They have an important bearing on the value to the refiner of raw sugars. He gave his methods in detail. It was an excellent paper.

Dr. GRINNELL JONES of the Tariff Commission described The Citric Acid Industry. He recited the crude methods in vogue in Sicily and the mechanical devices and stratagems that are current in California. He also gave some of the perplexing problems that are likely to come before Congress in the decision of tariff duties on citric acid. In the meantime, of the two products that are sold in competition, tartaric acid will be produced in decreasing quantities if we have nation-wide prohibition, while the makers of edible lactic acid declare themselves to be marching into the market with their wares at a lively pace. Citric acid is made from cull lemons and the greater the demand for it, the more severe is the grading of the fruit and consequently the better is the quality of the fruit marketed. In Sicily the culls often are as much as 40 or 50 per cent of the crop whereas in California, with greater attention to the trees, the culls are seldom above 10 per cent of the crop.

Professor ALEXANDER SILVERMAN of the University of Pennsylvania described his invention of A New Illuminator for Microscopes, using lantern slides. This was his second paper on the subject showing a number of improvements. We have already described the illuminator in a previous issue<sup>1</sup>.

#### DEOXIDIZING STEEL WITH FERROMANGANESE

Mr. ALEXANDER L. FIELD, at the continued session of the Division on Thursday morning read a paper on The Deoxidation of Steel by Ferromanganese. The speaker discussed the function of manganese in steel and admitted that it is not known. He was convinced that the theoretical reaction of  $\text{FeO} + \text{Mn} = \text{MnO} + \text{Fe}$  does not take place. On the other hand manganese combines with sulphur to form manganese sulphide which is less harmful than the iron sulphide. When steel solidifies it gives off 24 times its volume of gas, and analysis of that from steel which has been treated with the usual amount of ferromanganese and ferrosilicon shows 3.6 per cent Cl, 0.9 per cent O, 30.5 per cent CO, 52.1 per cent H, 0.2 per cent  $\text{CH}_4$ , and 12.7 per cent N. He considered the manganese reaction to be more probably  $\text{FeO} + \text{Mn}_2\text{C} = \text{Fe} + 3\text{Mn} + \text{CO}$ . The paper was one of considerable extent and its content is but partially indicated in the foregoing.

#### WAR'S EFFECT ON COTTONSEED OIL

Dr. DAVID WESSON of the Southern Cotton Oil Co. discussed The Cotton Oil Industry in the War, illustrated with lantern slides. Before the war mills had trouble in getting seed because mill owners could not compare the prices they paid for it or even talk about

them with a view to agreement without the danger of being sent to prison. Now Uncle Sam fixes the prices and if a mill owner does not live up to them he loses his license. Dr. Wesson did not complain; he merely observed that things were different from the way they used to be. The amount of oil per ton used to vary according to the quality of seed. Now 135 lb. per ton must be squeezed out anyway. And owing to the need of linters for nitrocellulose, every ton must furnish 145 lb. of lint which makes it necessary to keep the saws in perfect order. Owing to the demand for fats some 1,700,000 bbl. of other oil has come upon the market. In districts where the boll weevil ravages the cotton fields the farmers have taken to growing peanuts for their oil.

A paper by Mr. J. F. G. HICKS on Yttrium Mixed Metal was read in his absence. He described the metal as burning in the air in a manner similar to magnesium and said that it decomposes water with considerable energy. It is very difficult to prepare and it gives off an odor of something like calcium carbide. He believes it to have value in alloys with other metals and is engaged in more extended experiments which he will report later.

#### GILSONITE SHALES AND GASOLINE

Mr. GUSTAV EGLOFF described the conclusions reached by Mr. Robert Moore and himself on gilsonite. They have been working on shales to determine the amount of bituminous material to be recovered from them. Gilsonite is a pure bitumen found in Utah in large quantities and is used in rubber, lacquers, pipe-coating, etc. It melts at about 300 deg. They distilled it at atmospheric pressure to find the yields of motor spirits or fuel oil and ammonium sulphate available. By destructive distillation they obtained at the rate of 160 gallons of fuel oil of sp.gr. 8.8, or 29.4 deg. Bé. per ton. The ammonia yields were too erratic to report. From the recovered oil they got a gasoline fraction of 20 per cent. But while it has the volatility of cracked gasoline it would not serve on the market in its place. It has a light lemon-yellow color when first distilled which turns to a deep red on standing. This they were unable to remove. It also contains nitrogen, sulphur and oxygen compounds. Their results have but negative value at present because gilsonite now sells at from \$60 to \$70 a ton and it would be ridiculous to think of making fuel oil from it at such a cost. But the shales are on hand and there are reasons for addressing ourselves to the subject of their use with intelligence.

The petroleum supply is growing short. The Geological Survey estimates that the total available oil in the United States was originally 7,000,000,000 barrels. Since 1859 we have taken out 4,000,000,000 bbl. leaving 3,000,000,000 bbl. still to be produced. At present rates our petroleum deposits are likely to be exhausted in 15 or 20 years; therefore we must look around for other sources of supply.

Shale contains many times this quantity. It is held that over 20,000,000 bbl. of oil may be extracted from the Colorado shales alone which contain from 2 to over 90 gal. per ton and may average around 20 gal. and 15 lb. ammonium sulphate. And yet despite the lurid articles in the daily press telling how to get rich quick on shales, and the offers of stock to investors with

<sup>1</sup>Published in this journal, March 15, 1918 and Sept. 28, 1918.

the assurance that they are coming in on the ground floor and that all they have to do is to put up their money to become millionaires, the investment outlook is far from promising. No technical work has been done so far, and the cost figures that the speaker had seen had been based entirely on laboratory experiments. Again oil that is drawn from the earth is still cheaper. We have the 3 billion barrels left to compete and 300,000,000 barrels available in Mexico. The entire problem needs working out. Mr. Egloff doubted if an investment of less than \$100,000,000 would see the industry organized, established and equipped to market its production. He expressed serious doubts as to the wisdom of investing in the shale-oil industry at present except for a long wait.

A second address by the same author was on The Steam Distillation of Gasoline. In this Mr. Egloff argued in favor of straight firing in preference to using steam and claimed a large economy in favor of it.

An abstract was read of a paper by Mr. HARRY F. LEWIS on The Quantitative Estimation of the Important Constituents of Crude Anthracene.

#### GROWING SUGAR CANE UNDER PAPER

Mr. H. E. HOWE of Arthur D. Little, Inc. gave the substance of a paper of Dr. Arthur D. Little on The Eckhart Method of Sugar Production. This consists in what is called "row mulching" under Eckhart patents whereby the rows of young cane are covered with a specially prepared paper which the sharp rigid young sprouts penetrate in growing while the weeds curl up under it and die. In the Hawaiian climate with its high temperature and heavy rainfall the growth of weeds is exceedingly prolific so that the cost of labor in weeding becomes a leading item of expense. By this means 70 per cent of the labor cost is eliminated and an increase of 25 per cent in the yield of cane is obtained. A method to make the special paper from excess bagasse was developed in the Little laboratory and a paper mill for the purpose is in progress of erection in Hawaii.

#### STANDARDIZING ODORS AND STENCHES

Mr. V. C. ALLISON presented a paper for himself and Mr. S. H. KATZ on An Investigation of Stenches and Odors for Industrial Purposes. The use of various substances having high olfactory properties has long been availed of for warnings in mines, to determine the tightness of joints in plumbing, to observe the circulation of ventilation and for other purposes. To aid in determining the best materials for this purpose the authors have constructed what they call an odormeter whereby the degree of concentration may be approximately determined. A sensitive nose on the part of the operator is required. Five empirical degrees of increasing intensity were fixed upon and by this means they were able to divide the materials to be tested into three general groups. Those of the first group become evident to the olfactory sense in dilution of 5 parts per million of air. The second group require 100 parts per million and the third, 1000 parts per million.

So far as we are aware this is the first instrument designed to establish olfactory standards and we sincerely hope that studies on the subject may be continued.

Mr. H. E. HOWE concluded the session by an illus-

trated description of the industrial research and testing laboratory of Arthur D. Little Inc. at Cambridge, Mass., which we have already described in a previous number of this Journal<sup>1</sup>.

#### POTASH SYMPOSIUM

This was held under the auspices of the Division of Industrial Chemists and Chemical Engineers and it was made a part of the general session.

Mr. J. W. TURRENTINE of the U. S. Department of Agriculture spoke on the Experimental Kelp Potash Plant of the U. S. Dept. of Agriculture. Research began in 1910, being instigated by the Bureau of Soils in the belief that other things besides potash were available from it. A Congressional appropriation was finally made and a plant costing about \$100,000 has been in operation since the end of August, 1917. It has a theoretical capacity of 150 to 200 tons daily but treats about 80 tons, owing to difficulties of harvesting. The kelp is stored and dried by direct heat in rotary kilns, the current of heat opposing the run of kelp. In the government plant the kelp is substituted to destructive distillation in vertical retorts, the charred residue containing KCl, iodine and NaCl. This is dissolved and evaporated, the sodium and potassium salts being separated by fractional crystallization. The work on distillation products, which stand between those of wood and coal, is not complete. The results so far are interesting and encouraging but not yet ready for reporting. Under present conditions the plant meets operating expenses.

In regard to the subject of potash in general Mr. Turrentine considered the prospects of the several supplies respectively from Nebraska lakes<sup>2</sup>, Searles lake<sup>3</sup>, kelp<sup>4</sup> and cement dust<sup>5</sup>. The raw material of the Nebraska lakes contains the highest percentage of potassium and this was the source of the greatest supply last year. Although commercially successful at present they are threatened with early exhaustion. On the other hand there appears to be subterranean deposits of brine which are in part drawn upon now. No prospect of great deposits similar to those found in Germany or in Alsace was mentioned in this connection.

Dr. F. W. ZERBAN spoke of A Useful By-product Obtainable in Potash Manufacture. He referred to a decolorizing carbon of very high potentiality obtained from the kelp char. The best results are obtained by carbonizing the unleached char quickly under conditions in which the gases may easily escape.

Dr. W. H. ROSS was absent on military duty and an abstract was read of his paper on The Extraction of Potash from Cement Mill and Blast Furnace Dust. The potash content of cement dust varies from 2 to 20 per cent K<sub>2</sub>O. The main difficulties are involved in the cost of transportation of the dust and in the fact that the potash recombines to form insoluble silicates. This can be made soluble again by digestion under pressure in the presence of lime. Generally speaking 75 per cent of the potash in cement dust is in soluble form.

Mr. H. W. STOCKETTS gave a talk on The Potash Situation. He emphasized the fact that of two factors necessary to food production we had been in the habit of

<sup>5</sup>This Journal, Sept. 25, 1918.

drawing upon foreign countries. The labor we got from anywhere except the Orient. In regard to the other factor, fertilizer, we drew our potash from Germany, the pyrites for sulphuric acid to make acid phosphate we drew from Spain and the fixed nitrogen we imported from Chile.

The development of the greensand deposits of New Jersey has been progressing on a limited scale. The cost is less than \$1 per unit of  $K_2O$ , obtained by digestion under pressure with lime. There are also in Colorado some ten million tons of tailings from gold mills that contain about 10 per cent of potash concerning which the prospects are favorable. Mr. Stocketts believed that some sort of a subsidy from the Government to prosecute research in this respect is under consideration.

Mr. GRIMWOOD, formerly of the Trona Corporation, was invited to speak. A new company called the Boro-solvay Co. has entered the field organized by the Pacific Coast Borax Co., and the Somet Solvay Co. of Syracuse, N. Y., and is now operating. The speaker is engaged in the construction of a plant for a third company which looks forward to the production of 250 tons daily.

#### SOCIAL FEATURES OF THE MEETING

On Tuesday evening an informal dinner took place at the Hotel Statler at which no speeches were made; but during the meal a most obstreperous Jazz band provided the now popular tumult, thumping and dissonances. After dinner a smoker was held in the same room. The band remained and besides this there were speeches and songs. On Wednesday evening a reception was held at which Dr. CHARLES H. HERTY read Dr. Nichols' presidential address. It was entitled "A Retrospect and an Application" and gave from the writer's personal experiences, an interesting history of the beginning of the American Chemical Society in 1876, and it told of the doubts entertained that a society could be organized upon such a subject as chemistry. Its present membership of over 12,000 was due to friendly coöperation and Dr. Nichols made an earnest and eloquent plea for that kind of working together that looks to the general welfare, declaring that success in its true sense consists far more in making the most of ourselves than it does in the acquisition of property.

On Thursday evening the Society was entertained at the Country Club at a delightful dinner by the Grasselli Chemical Co., and on Friday most of the members who remained made a trip either to Akron or to Wadsworth, Ohio, to visit the industrial establishments at those places. Other excursions to visit the Cleveland sewage plant, the steel industries of the city, and to Oberlin to look over the college and its chemical laboratory, Wednesday afternoon.

In the foregoing we have reported only the general meeting and those held under the auspices of the Division of Industrial Chemists and Chemical Engineers. We have had no opportunity to confer with the authors of the various papers and stand open to corrections for errors and omissions.

A feature of special interest at these meetings is the frequent opportunity for informal discussion which occurs. This has to do not only with current research but one is frequently reminded of research which has

been recorded and forgotten. As an example of this our attention was called incidentally to a paper by Jovitsch, a Russian chemist, recorded some ten years ago either in the *Journal* of the Russian Society of Physical Chemistry or the German *Berichte*; the relator could not remember at the time. Jovitsch passed ethylene and acetylene, in separate experiments, through a heated tube in the presence of a silent discharge. From ethylene he obtained a solid condensation product,  $C_{10}H_8$ , which had strong radio-active properties. From acetylene he obtained a condensation product  $C_{18}H_{12}$ , with still stronger radio-active properties. He was unable to account for all the carbon originally present and he argued from this that along with his condensation products he had obtained a highly radio-active new element. In view of the great need of radio-actives, the experiment would seem worth looking up and confirming.

Other sections in which papers were read were: Agricultural and Food Chemistry, Pharmaceutical Chemistry, Biological Chemistry, Fertilizer Chemistry and Organic Chemistry.

### World's Leading Filters on Exhibition

THE National Chemical Expositions have always been an opportunity for machinery manufacturers and especially for the filter companies to render definite service to the chemical and allied industrial concerns by exhibiting their latest improvements so that the prospective purchaser can conveniently decide which machine is the best for his requirements. Certainly never has the chemical manufacturer had a better opportunity of making the right selection than at this Fourth Chemical Exposition in which the excellence of the filter exhibits surpasses all previous shows. In no place on the globe is it possible to view such an array of filtration machinery. The world's best at its best is here displayed so that the superintendent or the manager in an hour or so gets the several points of advantage in the different competing machines that he could not possibly get in days by interviews with representatives or by poring through the literature of the several companies.

It is becoming more and more acknowledged that of the different types of filters some are better adapted to handle certain materials and others other liquors, such that the manufacturers are recommending different machines for varying kinds of work and the several companies are to a certain extent specializing in specific fields.

With materials requiring a simple dewatering, i.e., the separation of the liquid from the solid with the solid discharged as a transportably dry material it is but necessary to determine if they can be effectively handled in the continuous type of filter which have so advanced in their operating efficiency that they are admitted to be the leading type of machines for this class of work. The Oliver Continuous Filter Company in their Oliver filter, the Industrial Filtration Company in their zenith rotary filter and the United Filters Corporation in their American continuous suction filter are the leading manufacturers of this type machine and each has a comprehensive exhibit making it a simple matter for the buyer to make his decision. If the material cannot be handled in a continuous vacuum machine but a self dis-

charging pressure can be adapted, as is often the case when high temperatures are required, the Sweetland and Kelly filters as put out by the United Filters Corporation or through E. E. Lungwitz, who handles Kelly filters, will be found to be efficient and economical machines. The Atkins Shriver automatic discharging plate and frame filter press is a new type recently developed for which much confidence is felt of its proving in practice to be another type applicable for this duty. This machine will also augment the work of the familiar plate and frame filter presses as shown by the Shriver Company and the Provost Engineering Co. which are still the leading machines for delivering dry cakes which have to be kiln dried or which have to be shipped as discharged from the filter.

In those plants where the material handled requires the solid to be washed free of soluble prior to discharge a modern filter is the rational choice provided the deposited solids are capable of discharge from the filter medium. If a sufficient wash is obtained on passing the cake through an atomized spray wash water without submergence the continuous filters pointed out above offer the best selection. Superintendents will find that the old objection of the spray permeating the entire filter room is now obviated by housing the sprays and much more adequate wash is being obtained by better control of the vacuum during the different operations as well as by using weak liquor washes. For those liquors requiring pressure type filters or those needing prolonged washing periods with the cake completely submerged the Kelly and Sweetland filters are first choice and especially the latter where the cakes can be uniformly built and the excess unfiltered liquor minimized so that the wash water may be turned on directly without draining the excess unfiltered liquor. Materials handled by plate and frame presses are more thoroughly washed when a refiltration of the cake puddled with wash water is practiced although washing type filter presses may be used to effect a superficial wash.

For liquors containing small amounts of a difficultly filtered solid which is a waste product and to which Filter-Cel may be added as a filter aid the Sweetland sluicing type filter has well earned the premier position. In such clarifying problems thin cakes only can be formed and the immense filter area obtained by putting the filter leaves of this machine on close centers as well as the ability to clean the cloths conveniently and without opening the filter account for the popularity of this type of machine.

In handling acid liquors each of the manufacturers are recommending special equipment. The Shriver and Provost Engineering Companies offer their wooden plate and frame filter presses, the Industrial Filtration Company their acid proof rotary filter and their open tank vacuum leaf filters of wood or lead lined construction, the Oliver Continuous Filter Company their acid proof Oliver filter and the United Filters Corporation their lead lined Sweetland filter and acid proof American filter. Cotton and woolen fabrics are the filter media used and if the precaution is taken of keeping the medium wet when the machine is idle so that the acid does not concentrate with the drying of the cloth a good length of life can be obtained.

Alkali liquors were once thought impossible of handling in modern filters but Sweetland's patent metal-

lic filter cloth put out by the United Filters Corporation and the metallic filter cloth, patent on which is soon to be issued, of the Newark Wire Cloth Company have changed this so that it is now practical to handle even the heaviest of caustic liquors with marked efficiency. In some cases a scale formation must be removed by periodic acid washes but the cloth otherwise stands up practically indefinitely.

The art of filtration abounds in "tricks of the trade" so that different methods of operation of a single machine will often vary the efficiency obtained through wide limits. Yet some materials offer such obstinate difficulties that special machines can more effectively handle them, hence the zenith continuous rotary hopper of the Industrial Filtration Company and the continuous sand filter of the Oliver Continuous Filter Company. Each of these machines is primarily designed to handle those liquors the solid content of which is free filtering and of a tendency to rapidly settle. The application of these machines is also proving more and more advantageous as a substitute for centrifugals in drying crystals from the mother liquor.

Some radical improvements feature some of the exhibits and are worthy of note. The United Filters Corporation are showing a new design of hinge on their Sweetland filter which not only is simpler than their previous eccentric hinge but is also capable of more positive and convenient adjustments. Lugs are cast on the rear of the upper half and drilled to accommodate swing bolts which are adjustable at the top. The lower end of the swing bolts terminates in a forked hinge bearing on which the lower half is suspended. Adjustment is made by moving the nuts on the top of the bolts and obviates such accurate machining as was required with the older type hinge. The American continuous suction filter is now being supplied with a receiving pan continuous in the rear of the machine instead of individual pans as formerly built which allows of greater accessibility and better control of the overflow.

The Atkins Shriver automatic discharge filter press has been redesigned so that by use of a friction clutch no excessive load can be put on the driving mechanism and the paddles are being made of cast iron shaped so as to allow the dislodged solid to more easily escape to the central discharge outlet. The paddle shafting has been strengthened so that the paddles travel in a fixed position, thus insuring freedom from the plows digging into the cloth. This machine abounds in unique mechanics and is held to be practically fool proof now.

The acid proof Oliver filter of the Oliver Continuous Filter Company is now equipped with lead plates covering the sides of the machines and as the axis of the filter is located above the maximum level of the liquor in the lead lined pan rigid iron construction is provided without the metal coming in contact with the liquor.

---

**Phenol from Mono-brom-benzol.**—It has been generally accepted heretofore that the halogen compounds of benzene were not suited for the manufacture of pure phenol. Mr. HERBERT H. DOW of Midland, Michigan, patents a method of causticizing  $C_6H_5Br$  with dilute aqueous solution of  $NaOH$  at 300 lb. per sq. in. pressure (425 deg. F.) in an autoclave as follows:

## Wood-Waste as a Source of Ethyl Alcohol\*

The Economic Causes for Past Failure in This Industry—Co-operation of Lumber Industry Essential to Success—Technical Problems Solved—Costs at Fullerton, La.

By GEORGE H. TOMLINSON

FOR some years we have been hearing more and more regarding waste wood as a source of ethyl alcohol. The amount which is thus being made, however, is still but a fraction of the nation's supply and within the past few years has not been extended irrespective of the great and increasing demand which the war has developed.

It may be advanced that sufficient capital is available and competent technical skill can be secured; but if the proposition is, therefore, all that has been claimed, the question naturally occurs. Why has more rapid progress not been made? Is the proposition fundamentally unsound, or does it still offer the very considerable possibilities which have been predicted?

We all realize the distance to be traveled between the discovery of a chemical reaction and its successful commercial development and application. In this case, as a matter of fact, one hundred years have already elapsed. The pitfalls to be crossed, both technical and commercial, are legion, and the more unusual, attractive or revolutionary the proposition may be, the more difficult may its pathway become. Premature development and extravagant or unsound exploitation can prostitute an undertaking, no matter how promising it may be, and when this occurs in connection with a process which has not been already established, disaster is invited.

### INDUSTRY DAMAGED BY PREMATURE AND UNSOUND PROMOTION

I think I may safely say that such a condition of prostitution represents the present status of this particular industry and explains to a large extent its present position of apparent stagnation, even at this time when its further development should offer such unusual opportunities.

In this connection the several company flotations which have occurred have been initiated by promoters having no particular interest in the business itself. This has resulted in only a small portion of the rela-

tively large amount of capital which has been raised in connection with the undertaking filtering through for its actual development. Adequate research has not been undertaken, the plants which already have been constructed have been started prematurely in locations having little regard to the commercial conditions involved, all in order that a rapid showing might be realized and a quick turn made by the promoters. Any complete consideration of this aspect of the proposition can only lead to the conclusion that the miracle is that anything has survived. The fact, however, that several million gallons of alcohol have actually been produced from this source, and that at least two plants have been operating more or less continuously over a period of years, irrespective of the technical and commercial handicaps from which they still suffer, justifies the belief that ultimate success is established, and that the undertaking offers much promise for the future.

It was originally assumed that almost every sawmill represented a possible location for the establishment of such a plant. Since there were almost innumerable sawmills at which the disposition of wood-waste was a problem, even constituting in most an element of expense, it was also assumed that this material could be purchased at a purely nominal figure. It therefore seemed logical that favorable contracts for wood-waste could be made, and, having sufficient capital, the company controlling the process could establish an endless chain of plants producing ethyl alcohol, and thus soon secure entire control of the alcohol market.

On this basis and plan the business was projected. It was soon found however, that while there was no question regarding the number of sawmills or the extent of the waste wood which is produced, nevertheless there are very few at which conditions are entirely favorable for the establishment of the extensive plant which the manufacture of ethyl alcohol requires. The life of the lumbering operations may be uncertain, the water supply deficient, labor or transportation operations unfavorable, or any one of a number of such factors may be found which jeopardize success.

\*A paper read at the Fourth National Exposition of Chemical Engineering, Sept. 25, 1918.

The fact that sawdust and all the other forms of waste wood are so bulky and difficult to handle precludes transportation, and therefore confines its processing to the point at which its production occurs. When approached, the lumberman who has a suitable location soon recognizes the advantage which he enjoys, and any outside company wishing to do business must pay his price, and if once established has no other source of supply. It can at once be seen that any large or general development along these lines was impractical and bound to fail.

#### A NEW START MUST BE MADE ALONG DIFFERENT LINES

In the manufacture of our lumber we know that many millions of tons of waste wood are annually produced, and the potential asset which this waste represents is being recognized. If any considerable part of this, however, can be converted into alcohol, there is probably no more important industrial use which it can be made to serve. That this can be done in a limited way has now been completely proved, but in order to greatly extend its application, the development, it would seem, must follow different commercial lines from those along which the start was made.

The process which has been developed naturally divides itself into two very distinct and separate steps. We first convert a certain portion of the wood, amounting to a maximum of about 28 per cent, into soluble carbohydrates which are then separated in the form of a clear solution which normally contains from 10 to 12 per cent. As a second step we have the fermentation and distillation of this product for the production of ethyl alcohol. It is not essential that both of these operations be conducted at one point, since the sugar solution can be evaporated, and then becomes quite the equivalent of cane molasses, which at present constitutes the principal source of our alcohol supply. Molasses, as we know, is transported to, and assembled at, the most favorable locations for alcohol production, there to be manufactured on the largest scale. Applying this same principle we immediately find that the scope of the wood process is greatly extended. Not only can wood-waste be utilized at those comparatively few locations at which suitable conditions for the manufacture and distribution of alcohol are found, but almost every sawmill with an assured capacity for a reasonable period can be considered as a possibility. At the most desirable locations, complete installations for manufacturing alcohol can, of course, be made; at the others molasses plants

can be installed and their product transported to existing distilleries or to new ones at which the product of several such units can be assembled and used.

The investment required for such a molasses plant is small compared with that which the complete distillery involves, and the importance of this can at once be seen in extending the scope of the undertaking. Furthermore, smaller units can be operated economically, less skilled labor is required, and it does not come under the exacting regulations and control of the Internal Revenue Department as is the case if alcohol is produced. Furthermore, if the molasses product is sold to those already engaged in the distilling business, many market and other trade difficulties are removed which only those having experience in the alcohol business fully appreciate and which the smaller producer might be unable to overcome.

#### LUMBERMEN MUST COÖPERATE AND TAKE ACTIVE INTEREST

In order that such a plan may be carried out, however, it would seem that proper headway cannot be made unless the lumbermen themselves assume the initiative, or at least give it their most sympathetic coöperation and support.

In order to operate to the greatest economy, such a plant should preferably constitute a part of the lumber operation itself, being operated under the same management and on the same premises, thus avoiding all unnecessary handling and storing as well as duplication of equipment or staff. In addition to this, the lumberman, controlling as he does the raw material, can alone determine and regulate its most economical disposition and use, and unless he is financially interested in the subsidiary company its supply of raw material can never be fully assured.

The lumbermen, however, are naturally cautious about engaging in enterprises apart from their regular trade. In the past, numerous byproduct ventures which have been taken up in connection with the lumber industry have failed and very few have succeeded. That this has been due either to their being entirely impractical or as a result of incompetent technical advice is probably true, but nevertheless these failures have seriously retarded others from embarking in the line.

In this case, however, the uncertain and costly experimental expense has already been borne by those that have been blazing the trail, and the success of the enterprise from its technical aspects at least is demonstrated.

It now remains for some one to make a fresh start and thus step in and take advantage of the mistakes of the past. If this is done along sound business lines by one of our progressive lumber concerns, complete commercial success appears inevitable. Should it be found that progress along these lines is blocked as a result of patents, those controlling such patents would be well advised to accept an equitable royalty in order that a proper start should be made. Once this step is taken, others will follow and real headway then be made.

#### PRODUCTION OF MOLASSES SHOULD APPEAL TO LUMBERMAN

From the lumberman's point of view, the production of molasses should offer a very strong appeal. While there are at least several profitable uses to which his waste can be applied aside from its use as fuel, the others, as far as I know, demand sorting or selection. In the case of producing molasses or alcohol, any part or all of his waste can be used even including that which constitutes his fuel supply, since the residue left after extracting the sugars, representing 70 per cent of the original amount, is not depreciated in fuel value. In other words, that portion which is actual waste and is being destroyed can be combined with the amount being burned for fuel, and 70 per cent of this total will still be available for power development. In considering and comparing the values extracted, it is therefore necessary to consider also the much larger tonnage which this process utilizes. The cost of production compared with the cost of cane molasses, however, is the vital element upon which this development must ultimately depend.

In June, 1913, the costs given below were obtained in the alcohol plant then operated by the Standard Alcohol Co. at Fullerton, La. The actual cost of this plant at that time amounted to \$456,920.56. Of this sum, about \$200,000 represented the expenditure for the plant and equipment involved in the conversion of the wood into sugar and the separation of this in the form of a solution. The balance was required to provide the necessary plant and facilities for fermenting and distilling the latter and converting it into alcohol.

#### COST OF PROCESSING AT FULLERTON, LA.

Operations were conducted for 22 days at three-quarter capacity. During this time 6125 tons of green waste wood containing 48 per cent moisture was processed, giving a yield of 1,688,600 gallons of sugar solution averaging in strength 10.3 per cent.

The cost of processing this, exclusive of the cost of the wood, but including all other material, labor, power, factory expense and overhead, together with proper allowances for depreciation, amounted to a total of \$5,371.56, or 31.8 cents per hundred gallons of the strength stated. To convert this into molasses, the cost of the equipment for this purpose would have to be added to the cost of the plant and the cost of its operation to that of the product. However, since the residue from the process supplies the necessary fuel, this concentration can be effected at very little cost.

Assuming a concentration of 8 to 1, the resulting 12½ gallons of molasses which one hundred gallons of the dilute solution will yield may be figured at 2.5 cents per gallon or, say, 3 cents including the evaporation. This

is of course a lower figure than that at which cane molasses has been sold in recent years and very much lower than any price which may be expected to prevail in the future. What this price may be is problematical, but 12 cents is probably none too high.

When we compare the fermentable contents of the product of this run with that of cane molasses, the showing is not so favorable. During the month the average production of spirit amounted to only 4.87 proof gallons per 100 gallons of dilute solution. Using this same percentage, a gallon of wood molasses would yield only 0.39 gallons of proof spirit, whereas cane molasses yields practically gallon per gallon. This gives a cost of 7.7 cents for wood molasses to yield the spirit given by a gallon of cane molasses. While even on this basis it appears that a profit is fully assured, the result which this comparison gives is far from representing the best which can be obtained since the quality of this product was poor.

From the figures given it can be calculated that only about 8.5 per cent of the dry wood was converted into sugars which were fermented, although approximately 24 per cent of the wood was extracted in the solution obtained. It has been repeatedly demonstrated, however, on both large and small scale experimental operations that 26 to 28 per cent of the wood can be converted into water-soluble carbohydrates as a result of simple acid hydrolysis, and that under the best conditions over 80 per cent of this is obtainable in the form of fermentable sugar. In place of realizing this result, not over 50 per cent of the water-soluble carbohydrates obtained has actually been fermentable in the product of the plant which I have mentioned, and the average has been less.

#### PATENT CONFLICT HAS RETARDED PROGRESS

It remains to translate such experimental results, depending as they do upon the conduct and control of the chemical reactions involved, into commercial practice. To do this requires little change in the mechanical methods of handling which were used at Fullerton and largely developed by myself. The mechanical efficiency of these is indicated by the very low per-gallon cost which I have given and which there is no reason to believe should be increased in effecting the much more complete hydrolysis which it is easily possible to obtain. That this has not already been done, I attribute principally to patent conflicts which have directed this development along unnatural lines in the effort to avoid infringement and permit exploitation. In undertaking any new installations, however, if full advantage is taken of existing knowledge and the experiences of the past, the production of a wood molasses equal to cane molasses in fermentable value is assured, and at a cost per gallon which certainly should not exceed that of the low-grade Fullerton product which we have considered.

The lumberman already can see a limit to his timber supply and is rapidly being forced, for this reason, to recognize the necessity of conserving all that is left. Nevertheless, he is still burning 50 per cent of his logs either under his boilers or in his refuse destroyer. Every ton of this waste can be made to yield over 30 gallons of molasses without disturbing in any way existing methods of operation, unless it be that of the

expensive destroyer which every large sawmill still maintains. Allowing but three cents per gallon profit on the molasses which can thus be made, this would be equivalent to an additional profit of almost \$2 on a thousand feet of lumber, an amount probably quite equal to the average profit realized on the lumber itself. In this, it would appear that we may have an almost unlimited source of molasses within our reach, which the distiller can readily convert into the highest grade of ethyl alcohol without any, or little modification in the equipment which he already has at hand.

#### OPPORTUNITY FOR READJUSTMENT OF DISTILLING BUSINESS

With drastic prohibition as a probability of the future, as well as the necessity of conserving everything which can be used either directly or indirectly for food, this should offer a means by which the distilling business can readjust itself to meet these conditions, and at the same time provide alcohol in such quantities and on such a basis that its much wider industrial application becomes a possibility, with all the consequent commercial advantages to which this would lead.

With proper coöperation to this end between the lumber and distilling interests, it should be possible to rapidly realize this condition to their mutual advantage, and at the same time release for other use the immense quantities of food products now used for alcohol production.

When the facts which I have attempted so inadequately to present are more fully recognized, and the proposition is taken in hand by those having a vital interest in its development and success, it may be expected to become a business of the greatest magnitude and importance, and wood-waste should become the principal source of ethyl alcohol.

Niagara Falls, Canada.

**Separation of Aromatic from Paraffine Hydrocarbons.**—The addition of some suitable semi-miscible liquids to the mixed hydrocarbons obtained in the distillation of petroleum, to separate the aromatic toluol, bonzol, etc., by selective solution has been one of the important problems of the munition chemist, as no satisfactory direct distillation separation is satisfactory, the vapor pressures of the members of these series not having a sufficiently wide margin for making good fractionations. Liquid sulphur dioxide has been experimented with considerably in laboratory fractionations but is not practical for industrial use. FLETCHER B. HOLMES of Woodbury, N. J. (Assignee E. I. du Pont de Nemours & Co.) has found that dinitrotoluol is a satisfactory extractor and patents its use.

Gasoline containing the aromatic hydrocarbons is mixed in any suitable manner with an equal weight of a nitro-compound—dinitrotoluol being preferable. This mixture, when allowed to stand, will separate into two layers. The lower layer is comprised mainly of a solution of aromatic hydrocarbons with some paraffines in the dinitrotoluol. The upper layer consists of a solution of dinitrotoluol and some aromatics in solution in gasoline. The two layers are separated and distilled, the higher boiling point nitro-compound being readily fractionated from each. The distillation is carried on preferably at a reduced pressure, or by injection

of a current of steam or other inert gas through the liquid; as the separation from the nitro-compound may be more readily effected in this manner. A distillate will thus be recovered from the lower layer having a higher aromatic concentration, while the one obtained from the upper layer will be decreased in aromatics. Upon repetition of the process, the lower layer fractions will increase in their toluol, benzol etc., content, while the upper will decrease in aromatic content until totally extracted. (Aug. 20, 1918; 1,276,219.)

MR. EDWARD A. BARNES of Giant, California, has received a patent on a process for directly nitrating the aromatics in the petroleum distillate. The light distillate is clarified by repeated agitation with 96 per cent sulphuric acid in the proportion of one gallon to the barrel of oil until all the fluorescent bitumens are extracted. The cleaned distillate is then mono-nitrated with a determined amount of a mixture of nitric and sulphuric acids at as low a temperature as possible, when all of the aromatic hydrocarbons are obtained as mono-nitro-derivatives. A mixture of 625 weights of 70 per cent  $\text{HNO}_3$  and 325 weights of 96 per cent  $\text{H}_2\text{SO}_4$  are slowly added in the form of an atomized spray to about 5000 weights of refined gasoline contained in a vessel provided with stirring devices and cooling coils. The temperature is kept as low as possible and agitation continued for four hours, after which the contents are allowed to separate. Three layers are formed, the top one being essentially paraffine oils, the second about one-tenth the bulk of the first consisting of nitro-aromatic hydrocarbons with a small paraffine content, and the third spent acids with not more than  $\frac{1}{2}$  per cent of unused nitric acid—more than this amount indicating that too much mixed acid was used.

The mixture of nitro-aromatic hydrocarbons which represents 10 to 15 per cent of the original amount of distillate, dependent on the oil field from which it was derived, can be fractionally separated in any suitable still and condenser.

Furthermore, it is found that the complex mixture of mono-nitro-derivatives obtained in this process has the property of reducing the freezing point of nitroglycerin and that this property is also possessed by the mixture of di-nitro-derivatives obtained by re-nitrating the mixture of mono-nitro-derivatives with stronger acids at higher temperatures, and that all of these mixtures which range from liquids to solids are extremely suitable for employment in the manufacture of low freezing point explosives. The mixed acid employed for di-nitrating the mixture of mono-nitro-derivatives has a composition of 36 per cent  $\text{HNO}_3$ , 62 per cent  $\text{H}_2\text{SO}_4$ , and 2 per cent  $\text{H}_2\text{O}$ ; the temperature of reaction is 170 deg. F. For tri-nitrating, the strongest acids obtainable are used; 93 per cent  $\text{HNO}_3$  is mixed with oleum containing 20 per cent free  $\text{SO}_3$ , and the temperature is maintained between 210 and 260 deg. F. (July 23, 1918; 1,273,568.)

**German Sugar Production**, according to the *Kölnische Zeitung* is falling off from 28,000,000 tons of sugar beets in 1915 to 18,000,000, 1916; to 17,500,000, 1917. One-sixth of these figures gives the refined sugar tonnage.

# Advance in Industrial Organic Chemistry Since the Beginning of the War\*

A Review of the Expansion in American Organic Chemical Industries Since the War Began—Outlook for Future is Most Encouraging—Disturbed Trade Relations are Favorable to Establishing an Export Business

By SAMUEL P. SADTLER, Ph.D.

MANY ordinarily intelligent people with no special acquaintance with scientific matters will confess to having had the belief that the United States had no established chemical industries at the outbreak of the present great world war, or if we had any, they did not cover the field of what is known as organic chemistry. Organic chemistry was to them the field of coal-tar dyes and synthetic medicines. And was not this the peculiar and exclusive domain of the German chemical manufacturer? We rather think that this expresses the actual knowledge on the subject on the part of our non-scientific newspaper and magazine writers at the outbreak of the war.

However, the elements which go to favor the establishing of a chemical industry are a wealth of raw materials and a market for the manufactured product, and with these the coöperation of intelligent chemical effort and capital. All four of these elements existed in the United States and the result of their coöperation had already been quite effective long before the beginning of the war in giving us flourishing chemical industries based upon organic raw materials and involving applications of organic chemistry. When we recall the great wealth of this country in petroleum and asphalt, in all varieties of coal, in vegetable and animal oils and fats, in cereals of all kinds and in fibres of indispensable character, we would be surprised if flourishing chemical industries had not been established.

## MAGNITUDE OF THE PETROLEUM AND OIL INDUSTRIES

Let us briefly view some of these industrial organic developments as they existed prior to 1914. The American petroleum industry easily ranked as the first in importance in supplying the world with the various products of mineral oil. Of a total annual world's production in 1914 of over 400,000,000 bbl., the United States produced 265,762,000 bbl. or just about two-thirds, while Russia, the next in rank, produced 67,000,000 bbl. or 16.7 per cent of the total amount.

But it is not only the raw material production that is to be considered. By far the larger proportion of this crude oil was refined in the United States and from it were made gasoline, kerosene, lubricating oils in great variety, paraffin and paraffin candles, vaseline and similar products. These products were not alone for the American market but went all over the world.

We also had a great and well developed industry in the extraction, refining and working up of vegetable and animal fats and oils. A peculiarly American industry was the cottonseed oil and cake industry. Hundreds

of mills throughout our Southern States were devoted to the crushing of the seed and the preparation of the cake, while the refining of the oil and the making of the finest edible products was carried out in large plants. The enormous production of lard and lard oil by our great packing companies and the preparation of oleo oil for foreign shipment was also an important and well established American industry. As a side product, the extraction and refining of glycerin had also become well established and the American soap industry was also well developed and a large export business already inaugurated.

The utilization of linseed oil for paint oils and in the manufacture of linoleum and oil cloth had also reached a high development at the hands of American technologists.

## CORN PRODUCTS DISTINCTIVELY AMERICAN

The great naval stores industries involving the production and utilization of American turpentine and resin had also been well developed and many minor chemical industries based upon them. America was also one of the largest consumers in the world of rubber; thanks to the manufacture of all classes of rubber and water-proofed goods and to the utilization for automobile tires, the working of rubber had been extensively developed.

The refining of sugar, in part produced in the United States and the neighboring West Indies and in part from imported European raw beet sugar had become an extensive industry with the most modern of plant equipment and under scientific chemical control.

As America is in a large degree the granary of the world in its production of cereal foods, we had large chemical industries already occupied with the preparation of the special classes of food products of cereal origin. One of the best instances of a distinctively American industry developed from American material is the corn products industry. From the maize or Indian corn is produced corn starch for food purposes and for technical purposes, glucose or commercial dextrose, corn or maize oil and commercial dextrines. This industry has been developed from a distinctively American cereal and on lines quite peculiar to it as an industry of American growth.

Turning to the textile industries we have, as an American production, one of the world's most useful fibres, viz., the cotton fibre. I have already referred to its peculiar by-product, the cotton seed and its utilization. However, we have many important industries utilizing the cotton fibre in which its bleaching, dyeing and other treatment is chemically controlled.

The textile industries using wool and silk as well as

\*A paper read at the Fourth National Exposition of Chemical Industries, New York, Sept. 28, 1918

cotton have however attained a high development in the United States and the chemical side involving the cleansing and after treatment of the fibres had been thoroughly worked out.

The products of destructive distillation remain to be spoken of. Our American wood-distillation industry will be specially presented by another speaker during this Exposition and so I will pass this by. Coal distillation for gas-making had been practiced by the most accurate scientific methods and great varieties of special gas-making processes had been developed. It will be remembered that the Lowe water-gas process was an American invention which has been copied and adapted since in various other countries. However, we were slow to discard the old wasteful beehive oven for coking of coal for by-product ovens which collect the valuable residuals including gas, tar and ammonia. The production of coal-tar crude ingredients was therefore only moderately developed and of what we term the "intermediates" for the color industry, there was scarcely any production.

An American dye industry using imported intermediates therefore existed, but it existed under difficulty and played but a subordinate part in supplying the American market with the dyes required for our textile industries.

#### CAPITAL HAD NOT MADE THE ACQUAINTANCE OF THE CHEMIST

This brief survey shows that it is a great mistake to assume that there were no organic chemical industries existing in this country in 1914 at the outbreak of the war. Nevertheless the general public knew little of the chemist and his actual or potential value to industry or commerce. Capital, which frequently made large investments in mining and similar enterprises, many of which were largely speculative, had not made the acquaintance of the chemist to any notable extent perhaps because the language of chemical reactions was something foreign to his experience or training and hence distrusted. The war came and we soon learned how great a disturbance such a great war could be to the world's commerce in which the United States played a vitally important part. We also learned promptly how chemical industries were the foundation stones for this great commerce. It soon developed that war in its modern form was based upon the chemical activity and scientific development of a country and then the chemist began, as it has been repeatedly said, to come into his own.

Our special topic therefore is to briefly note how our American chemical industries, and in particular those involving organic chemistry, have responded to this war impulse and demand in the four years that have elapsed since the beginning of the war period in 1914.

Our petroleum industry, which we have shown was already in a highly developed state, had important problems at once presented to it. Great as was our refining capacity, it was utterly inadequate to produce in normal course the quantities of gasoline that were required. Besides the growing automobile consumption, the war demands for motor trucks and for aeroplane and tractor engines came as an added load on the industry. Because of the demoralization of the Russian oil production and the German occupation of Roumania,

the whole gasoline supply for the allied nations has to come from America. To meet this demand we have in addition to what may be called "straight refinery" gasoline, blended "casing head" gasoline and "cracked" gasoline. Under the pressure of the great demand, large quantities of volatile hydrocarbons are washed out by suitable solvents or condensed out of natural gas and then blended with heavy naphtha to bring down the gravity to a proper average. Such a gasoline will necessarily have a wide volatility range but is available for most uses of the normal refinery gasoline. Most of the areas producing natural gas are available for this gasoline extraction but it has developed particularly in West Virginia, in Oklahoma and in California. It is furnishing a rapidly increasing amount of gasoline yearly.

The third source of gasoline mentioned is from special cracking processes and it is this class of processes which has been attracting the most interest and giving the greatest promise of large results. The whole subject was discussed from a theoretical and historical point of view in *Bulletin* 114 of the Bureau of Mines by Rittman, Dutton and Dean. Since the date of that publication in 1916, a great deal additional has been published in the journals and much has been done in a practical way. The Burton process adopted by the Standard Oil Co. is now in operation on a large scale in several of the largest refineries of that company; the Rittman process has been tried on a working scale, although not yet developed to a final form for large-scale production; the McAfee process of decomposition in the presence of aluminium chloride as a catalyst has been developed by the Gulf Refining Co. and the Snelling process has also been brought forward.

That heavy petroleum oils can be cracked so as to produce much light oil or gasoline is beyond question, but the problem is to avoid the production of large proportions of unsaturated hydrocarbons which require acid treatment in the product. McAfee claims to avoid this production of unsaturated compounds and that his gasoline requires no acid treatment, but the success of his process is conditioned on the economical recovery of the anhydrous aluminium chloride available for use. Enormous quantities of other special petroleum products have also been called for by reason of war demands, such as high-grade lubricating oils. I had brought to me for testing some time back a "recoil oil," required by the Government for use with heavy guns, that with a high viscosity had to stand a cold test of — 5 deg. F. (— 20 deg. C.).

Then the demands of the English and the U. S. Navy for fuel oil have drawn upon the Mexican oil fields as well as those of Louisiana and Texas and have pushed production to the maximum.

Meanwhile a new raw material has been brought to notice that is capable of adding enormously to our available petroleum supplies in the oil shales of Western Colorado and Eastern Utah, the deposits also being found to some extent in Nevada, Wyoming and Montana. These shales readily yield by distillation a crude oil capable of furnishing gasoline, kerosene and paraffin and in addition large amounts of ammonia, so that sulphate of ammonia may be obtained as a by-product. In *Bulletin* 691B of the U. S. Geological Survey D. E. Winchester has described this occurrence and gives records of distillation. These shales are said to be like

the Scotch shales but richer in oil. With the gradual exhaustion of the oil fields they will prove a welcome addition.

#### VAST INCREASE IN OIL PRODUCTION AND IMPORTATION

The vegetable and animal oil markets have been greatly affected by the war and the industries based upon them have been changed in a revolutionary way in many cases. The first cause may be said to have been the export embargo established by Great Britain upon all glycerine-containing oils with the beginning of the war. Following this came a shortage in the cotton seed crop in 1915 and the introduction of Soya bean culture in the South. As the refined cottonseed oil took more and more the position of an edible oil, commanding correspondingly higher prices. The Soya bean oil took its place for industrial uses, for soap and paint manufacturers and as a constituent of compound lard and oleomargarine. Soya bean cake has also been readily taken up for stock feed and for fertilizer. The Soya bean contains more protein than either cotton seed or peanuts, as much fat as cotton seed, and only one-fourth as much fibre as cotton seed or peanuts.

It has a lower iodine number than linseed oil and is slow in drying, so that it can not completely replace linseed oil in the paint industry but can be admixed with it. Besides the production in the South, which according to Government reports in the year 1917 was from 531,000 acres, we have had an enormous development of the Soya bean oil importations as the following figures will show. Importation for year 1914, 12,500,000 pounds, for 1917, 264,900,000 pounds and for 1918, 336,824,646 pounds.

Most of this coming from Manchuria enters Seattle and other Pacific coast ports. All available storage facilities at Seattle and other coast points have been overtaxed in the handling of this supply.

#### HYDROGENATION GIVES OILS AN ADDED VALUE

Another great development in oil supplies has come from the greatly increased production of peanut oil. This has come to the fore as a salad oil and for soap making. The crop in the United States rose from 3½ million bushels before the war to 40 million bushels in 1916. For 1917, the Government reports shows that 2,277,000 acres were devoted to its culture in the South, and for the year of 1918 it is estimated that in the State of Texas alone 3,000,000 acres will be devoted to it. The importations have also increased sixfold since 1914, now amounting to over 8 million gallons.

A year ago we had no castor beans grown in this country to speak of. Today we have at Government instigation hundreds of thousands of acres devoted to it in Florida and elsewhere, with the product contracted for by the Government. As illustrating the greatly increased demand for oils capable of yielding food products we may also note the remarkable growth in the cocoanut oil and copra importations. In 1914 the importations of cocoanut oil amounted to 74,386,213 lb., in 1918 it had grown to 289,194,853 lb.; of copra for the expressing of cocoanut oil we imported 45,437,155 lb. in 1914 and in 1918, 486,996,112 lb. Similar changes have taken place in the fish-oil markets with the decrease in the menhaden catch, due to the commandeering of fishing boats and scarcity of men to man

them. Through our Pacific ports chiefly are imported quantities of dog-fish, halibut, salmon, sardine, shark, tuna-fish, candle-fish and walrus oils, largely new to the market, while whale oil, seal oil and porpoise oils are, again appearing in large quantities. These fish oils have moreover an added value as sources of supply since the general application of the hydrogenation process, whereby they can be changed into hardened fats without offensive odor and of the greatest value as soap stock and for glycerin production.

#### GLYCERINE AND OILS FOR EXPLOSIVES

With regard to the increased production of glycerine because of the war demand, I have no figures, but it has been very great, so that the use of glycerine in pharmaceutical preparations has been discouraged in order to conserve the glycerine for nitroglycerine production and for export to our allies. About 21 million pounds has been exported in 1918.

In the field of essential oils there are a few items of interest to note. With the study of wood turpentine as distinguished from gum turpentine it has been recognized that spruce-wood turpentine, now a waste product of the sulphite process of making paper pulp, has a peculiar composition. It consists largely of one aromatic hydrocarbon, cymene (iso-propyl-methyl-benzene). On subjecting this to the Friedel and Crafts reaction with aluminium chloride in the presence of an excess of benzene, toluene and cumene (propylbenzene) are formed. The toluene is readily converted into TNT (trinitrotoluene) and the cumene may be oxidized directly into benzoic acid. The work as reported in the *Journal of Industrial and Engineering Chemistry* for May, 1916, is still in a purely experimental stage but it has much promise.

One of the newer uses of essential oils which has particularly stimulated the production in the last few years of pine oil in the South is for the ore flotation process. The concentration of both copper and zinc ores in the United States as in other parts of the world is now effected by agitating the finely pulverized ore with water in the presence of a small quantity of oil. While fatty oils, mineral oils, coal-tar and wood-tar creosotes have been used, certain essential oils have been found to be specially adapted for this treatment. In this country pine oils, both steam-distilled and destructively-distilled have been especially used and quite an industry in these oils has developed. The magnitude of our copper and zinc production is such that although the amount of oil used in this flotation process is relatively small (less than 1 per cent on the ore) the aggregate consumption of oil is very large.

The war demand has greatly increased the call for rubber goods of all kinds, especially automobile tires, and consequently the consumption of crude rubber has grown rapidly. The importations of rubber in 1914 amounted to 132 million pounds but grew to 390 million pounds in 1918. Exports of rubber boots and shoes were valued at \$1,113,495 for 1914 and \$5,774,341 in 1918; the automobile tire exports were valued at \$4,068,639 in 1914 and \$15,128,294 in 1918.

#### VARIED USES OF ORGANIC SOLVENTS

In this connection reference may be made to the greatly increased demand for organic solvents and the

work done to meet this demand. The most important work of this kind is probably the production of acetone and similar solvents from the Pacific Coast kelp by the Hercules Powder Co. and this fortunately we will have specially presented at this time in a paper dealing fully with the subject.

Another promising line is the manufacture of amyl acetate from petroleum pentane recently described in the *Journal of Industrial and Engineering Chemistry* for July, 1918. This work has been carried out at the Mellon Institute in Pittsburgh, Pa. The use of these organic solvents is manifold but we may note the extensive use of pyroxyline solvents and the greatly increased use of lacquers of this description in the last four years. From aeroplane wing dope to artificial leather we have a variety of utilizations; some of these have grown to extensive industries within the past few years.

Closely allied with this industry is the artificial silk industry, one variety of which is made from a nitrated cotton or pyroxylin. Besides this variety we have the viscose variety, the cellulose acetate, and the cuprammonium artificial silk. The development of these products has been very great in this country in recent years, both for films and for artificial silk as a fibre increasingly used in the textile trade.

Industrial alcohol production has developed greatly in the past few years and numerous new plants have been established for its production from a variety of sources. Much attention has been given to a revival of the Classen process for hydrolyzing the cellulose of sawdust and fermenting the sugar produced therefrom. I have no reliable information however as to whether the difficulties which developed when it was first tried in this country some years ago have been sufficiently overcome to make it a dependable manufacturing process although it has attracted much newspaper attention. More reliable are the processes based upon the use of low-grade molasses and cereals of various kinds and a large production, at present taken over by the munition manufacturers, has been the result.

In addition to this direct war use much alcohol is made for denaturing and use in the manufacture of pharmaceutical products. Some 27 denaturing formulas have been allowed by the U. S. Internal Revenue office and these adapt it for use in a wide variety of cases where tax-paid pure alcohol is inadmissible on account of its cost. This form of utilization is not of temporary character as is the use in munitions manufacture but is destined to grow and require an increasing amount of alcohol properly denatured.

#### GREAT DEVELOPMENT OF THE DYE INDUSTRY

We come now to the industry which may be said to be the touchstone of our ability to achieve results under difficult conditions when confronted with an imperative necessity, viz., the building up on American soil from American raw materials with American capital and American chemical effort an independent dyestuff industry. In speaking of the conditions in the United States in 1914, I said that we had a small dyestuff industry, working under trade difficulties, for the most part with imported intermediates. There were, to be exact, five manufacturers, large and small, of dyestuffs in 1914. The tariff census of coal-tar products, as re-

ported for 1917, shows that there were at that time in the United States 81 establishments engaged in the manufacture of coal-tar dyes and 117 firms manufacturing intermediates. While these figures are striking and can not fail to arrest attention, it is only when we look more fully into the details that we get an adequate understanding of the great industrial achievement that has been wrought in the last four years.

First, as to our dependence upon foreign sources, chiefly German, for our dyestuffs at the beginning of the war in 1914. We were then making in this country a bare one-fifth of our needs out of foreign materials and had neither crudes nor intermediates to speak of. Dye imports from Germany in 1914 were valued at \$5,965,537; in 1916 they were valued at \$849, in 1917 \$464,499, and in 1918 at \$3048. The relatively large amount for 1917 represents shipments held at first in Great Britain but released later on appeal. Do we still import any dyestuffs? Yes. There are two reasons for importing from Switzerland and Great Britain mainly certain dye colors.

The new American dye industry did not at once attempt to duplicate the 900 or more supposedly distinct synthetic dyes of the German dealers but took up the most important classes and produced a moderate number of representative dyes, covering as far as possible the coloring or tinctorial needs of the textile trade. Some of the finer shades are still missing, hence the Swiss importations.

The other reason and perhaps the more important one was that Congress, in the enactment of our present tariff law, cut off the ad valorem duty on indigo and alizarine products, which caused manufacturers to leave the production of these very important products until they had covered the need in other groups more fully.

However, synthetic indigo of American manufacture is already on the market and there will be three sources of supply for it in 1918, one of which promises to supply at least one-half of what the American trade will need for the year. Similarly artificial alizarine of American manufacture, made in Brooklyn, in fact, will be available in large quantities from this time on.

Meanwhile approximately three-fourths of the dyestuffs needed are being produced and some colors in such quantity that an export trade has been started. Let us note that for the year ending June, 1916, the exports of all varieties of dyestuffs—aniline dyes, logwood extract and all other—totalled \$5,102,002 in value, but the bulk of these were vegetable colors including logwood extract. In 1917, the valuation of the exports had leaped to \$11,709,287, with an increasing amount of such colors as sulphur black and the simpler aniline colors. In 1918, and this shows the quality as well as quantity of development, the total exports of dyestuffs were valued at \$16,921,388. Of this, total aniline colors make \$7,298,298, logwood extract \$2,339,480 and all other \$7,284,110. It will be noted that the aniline colors alone exceeded in value the dyestuff importations from Germany in 1914.

#### HOW DOMESTIC SHORTAGE WAS RELIEVED

But the main market for which these dyes are being made, and for the permanent relief of which a great American industry has been created is the United States market and the way in which this has been done

is deserving of a more completely detailed examination.

With the shutting off of the foreign sources of supply in 1914, not only was the need of an American dye industry made clear, but the manufacture of munitions and the filling of foreign orders called for coal-tar products. The manufacture of phenol or picric acid and of trinitrotoluol all demanded an immediate supply of coal-tar crudes. So the gas works, the by-product coke ovens and the tar distillers all united for increased and intensive production. I need only refer to the lists of such great companies as the Semet-Solvay Co., the United Gas Improvement Co., and the Barrett Manufacturing Co. as illustrating the achievements in this production of coal-tar crudes. For the increased production of benzol and toluol the Ordnance Division of the War Department has also started to establish plants for by-product coal distillation because of its special needs.

However, for the dyestuff manufacture we go from the coal-tar crudes to the "intermediates." Some of these require very special apparatus for their manufacture and it was these that had not been made in this country prior to 1914. Our chemical apparatus manufacturers (several of whom are very well represented in this Exposition) responded to the call for this apparatus and gradually these important products, mostly new to American trade, were supplied. The tariff census of 1917 states that the production of intermediates for that year was contributed to by 117 firms and that the production amounted to 322,650,531 pounds valued at \$106,942,918. These figures however involve considerable duplication because of the use of some as a starting point in making others. That the amounts of many are very large is shown however by the statement published by the National Aniline and Chemical Co. that their Marcus Hook works has a producing capacity of aniline oil five times as great as the total consumption in this country prior to the war, and that this company is now the largest producer of aniline oil in the world.

Of course the manufacture of munitions, begun on Allied account and continued later by the Ordnance bureau on our own account, means the production of numerous organic compounds on a scale totally beyond any previous experience—picric acid, trinitrotoluol, nitrocellulose and nitroglycerine for smokeless powder, fulminate powders and other preparations are manufactured by tons, but as this is a war industry and not one that will continue we have omitted it from our discussion.

In conclusion, what is the outlook for industrial organic chemistry in the immediate future in this country? I would say that it is most encouraging. The exigencies of the war in Europe have caused a widespread search for independent sources of raw materials to be made and with very satisfactory results in many cases. Our large corporations have established research laboratories with the best up-to-date equipment and have planned real and thorough-going research in a broad intelligent spirit which does not ask for hasty results but emphasizes the wish for thoroughness. Our Government has recognized in a very satisfactory way its need of chemical service and has thus publicly endorsed the fundamental importance of the chemist in industrial achievement. Capital has come forward willingly in support of properly planned

chemical undertakings and thus made the establishment of new industries possible in a way far beyond what had been possible before the war period. Lastly, the disturbed condition of all European trade relations has made it possible for the United States to inaugurate very promising export business in quarters not previously practical or under conditions formerly distinctly unfavorable. These new achievements we have every reason to expect to continue in future and no doubt with added momentum.

### Charging Tar in Gas Producer

A new method of enriching producer gas contained in a description of the "Gasteam Plant at Ford City, Ontario" appearing in *Power* for Aug. 6, 1918, is an account of their success in returning tar recovered in their gas cleaning system to the producer for gasification. At this plant are installed two Smith gas producers, each built in six independently controlled sections, and with a total capacity of 100 tons in 24 hours. This gas producer has an incline grate with a heavy clinker bar at the toe of the slope, all of the grate bars being operated by compressed air. Each section is charged mechanically through an air lock at the top of the fuel bed, which latter is normally at a dark cherry-red heat and maintained at a depth of 5 feet at the top and 7 feet at the bottom of the slope. Exhaust steam is blown under the grate bars, thermostatically controlled so as to regulate the temperature of the blast at 120 deg. F.; too cool and dry a blast means hard clinker, while too hot a blast gives  $\text{CO}_2$  in the gas. The steam is blown into the producer in puffs, two per minute, so that the action somewhat simulates that of the Mond.

Each producer has its own gas-cleaning system in which the hot, dirty gas is first scrubbed in a primary cooling tower which reduces its temperature from 1100 to 120 deg. F. An exhauster, displacing 45 cu.ft. per rotation, delivers the cool gas under 3 pounds pressure to a series of seven tar extractors. These consist of 1½ pounds of spun glass-wool made into a diaphragm through which the gas passes at high velocity, leaving behind its tarry matters which agglomerate into drops and fall into a drain leading to a storage tank.

The stored tar is delivered to five sprays above each fuel bed through a 2-inch line, unjacketed, being blown out of the tank by 880-pound steam. This method is superior to pumping, since the steam blows out the entire system when it is empty, obviating any danger of plugging with solidified tar. About 950 gallons of tar are produced and consumed daily. Little trouble is had if the tar is sprayed evenly over a compact fuel bed running steadily at a temperature between 1000 and 1200 deg. F. Too high a temperature produces fine lamp black which clogs the clean-up system, while if the fuel bed is too cool, the liquid saturates the interstices. The use of the tar reduces the hydrogen and increases the methane content of the gas; it also betters the thermal efficiency of the producer from 8 to 9 per cent. Analyses of typical gases follow:

|                        | No Tar on Bed              |                            | Tar on Bed                 |                            |

## The Electrochemical Industries at Shawinigan Falls

Description of the Development of Over Three Hundred Thousand Horsepower and of the Varied Industries Attracted by This Resource—Conditions are Favorable for Labor, Raw Materials and Transportation

By HENRY C. RANDALL

SHAWINIGAN FALLS is located in the Province of Quebec, Canada, midway between Montreal and Quebec City, and derives its name from the Indian word indicating the resemblance between their beautiful quill and bead work and the great falls of the St. Maurice River. The city is of comparatively recent origin, having been until 1898 a wilderness, many miles from the nearest railroad. That year marked the commencement of the development of power at the falls of the St. Maurice River, which are 150 feet high at this point and offer what is perhaps the most remarkable natural power development in the world.

Since 1900 the growth of the city has been extremely rapid because with the coming of the Canadian Northern Railway and the Canadian Pacific Railway the products of immense electrochemical plants, which could obtain cheap power near the falls, were able to cheaply reach the world's markets. Twenty miles below Shawinigan Falls lies, Three Rivers, at which point the St. Maurice River enters the St. Lawrence River. Three Rivers is on tidewater, and with its many miles of docks, capable of docking any vessel navigating the St. Lawrence River, is in a position to furnish a remarkably satisfactory export shipping port for the industries which have grown up at Shawinigan Falls.

### POWER SUPPLY

The basis for the electrochemical developments at Shawinigan Falls is, of course, the large amount of hydro-electric power which is available at remarkably low prices. The Shawinigan Water & Power Company, which owns the power developments at this point, has at present installed in its generating stations at Shawinigan Falls and Grand'Mere, Que., 330,000 horsepower, of which 265,000 is electric power, the balance of 65,000 being sold as hydraulic power to certain of the local industries at Shawinigan Falls.

While this amount of power is capable of supplying all of the present requirements of the district, the Shawinigan company further owns the Gres Falls, six miles below Shawinigan Falls on the same river,

at which point 75,000 horsepower can be developed as soon as required. Moreover, at Grand'Mere, nine miles above Shawinigan Falls, provision has been made for the addition of 60,000 horsepower, and as the foundations have been prepared for this additional capacity, it could be obtained upon relatively short notice. The electrochemical industries at Shawinigan Falls are, therefore, assured of an abundance of hydro-electric power, not only for today, but for a considerable time in the future.

### SHIPPING CONDITIONS

Shawinigan Falls is served by two railroads, the Canadian Northern Railway and the Canadian Pacific Railway, both of which make connection with the National Transcontinental Railway a few miles from Shawinigan Falls. All switching to the various industrial plants is done by the Shawinigan Falls Terminal Railway, so that switching is conveniently and cheaply obtained and the facilities of each railway equally placed before all of the industries.

Three Rivers, twenty miles from Shawinigan Falls, is situated on tidewater, and will offer after the war, when shipping restrictions are reduced, an ideal export shipping port for seven months in the year. During the winter months when the St. Lawrence River is frozen over, export shipments are made from St. John or Halifax.

Three Rivers also offers an ideal shipping port for serving the Great Lakes trade, so that, especially in summer, Shawinigan Falls industries are placed very advantageously with respect to ocean and lake shipping.

While it is difficult to discuss export shipping rates at the present time, it is nevertheless true that in normal times, averaging a large number of the ordinary heavier electrochemical products, a differential of \$2 per ton exists in favor of Shawinigan Falls in summer, and \$1 per ton in winter, over Niagara Falls, which city is taken as representing the greatest electrochemical center on the continent. These differentials will, of course, only apply to products which can be exported to ports reached by the Canadian sailings,

FIGS. 1 TO 8.

Fig. 1—Canadian Electrode Co. Plant. Fig. 2—Shawinigan Electro Metals Co. Plant. Fig. 3—The Northern Aluminum Co. Ltd., Plant. Fig. 4—Canadian Ferro-Alloys, Ltd., Plant. Fig. 5—Shawinigan Developments. Fig. 6—Canadian Aloxite Co. Plant. Fig. 7—Canada Carbide Co. Plant. Fig. 8—Prest-o-lite Co. Plant.

which in general are satisfactory for supplying the European trade. If products are destined for ports not reached by Canadian sailings, it will in general be cheaper to use New York as a shipping point, in which case a differential of between \$1 and \$2 per ton exists in favor of Niagara Falls.

#### RAW MATERIALS

Bituminous coal in normal times is obtained from Nova Scotia, costing normally (pre-war) \$3.20 per ton on wharves at Three Rivers. Anthracite coal is

VIEW OF PORTION OF CHEMICAL SECTION

obtained from United States coal fields. Coke to the amount of about 200,000 tons per year is made at Montreal, largely from West Virginia coal, and can be obtained at very favorable prices.

Petroleum coke to the amount of about 5000 tons per year is manufactured at Montreal, about one-half being made from mid-continent crude-oil and the balance from Mexican crude oil.

Tar to the amount of 3,000,000 gallons per year is produced by the Montreal Gas Company, which is refined and from which 15,000 tons of pitch per year is available.

High grade limestone, quartz and sandstone are available in large quantities near the St. Maurice Valley. Chromium and titanium ores are found and mined commercially within one hundred miles of Shawinigan Falls, as well as zinc, magnesite and other minerals. Excellent shipping and railroad facilities, putting Three Rivers and Shawinigan Falls in touch with the world, make the supply of those raw materials required for particular processes a relatively easy problem for the manufacturer.

#### LABOR CONDITIONS

The St. Maurice Valley is essentially an agricultural community, and as it is largely populated with the thrifty and home-loving French race, there is available on the markets of the industrial centers food products at very fair prices, which is an essential condition in maintaining stable labor conditions. The large families which are common in the Province furnish practically all of the labor required in the industrial centers, and this labor, being French and thrifty, settles down and readily becomes a permanent part of an industrial community.

The amount of labor available in the Province is very

large and is of the kind adapted to industrial work, to which statement the large New England industrial centers of Manchester, Fall River and Lawrence bear witness, as the population of these cities is largely made up of French-Canadian people from the Province of Quebec. It is remarkable that in spite of present-day conditions no strikes or other great evidences of labor unrest have ever been found in the Shawinigan Falls-Three Rivers district. The natural traits of the French people, their thrift and frugality, make labor conditions in the St. Maurice Valley exceptionally satisfactory to the manufacturer.

#### GROWTH OF SHAWINIGAN FALLS

The first electrochemical industry to establish itself at Shawinigan Falls was the Pittsburgh Reduction Company, now the Northern Aluminum Company. Soon afterwards the Canada Carbide Company was started, and in 1905 the Belgo-Canadian Pulp & Paper Company built their first mill. These industries expanded rapidly to many times their original proportions, but no other industries were established at Shawinigan Falls until 1914.

During this period a very large market for the power generated by the Shawinigan Water & Power Company was built up throughout the Province of Quebec, transmission lines being built to serve all the larger cities of the Province and over a hundred of the smaller towns. In 1915, however, a very large addition to the generating capacity of the Shawinigan Company was completed, and this, with the great demand for power existing throughout the country and the inability of manufacturers to obtain power, made the growth of Shawinigan Falls extremely rapid from that time on.

The population of Shawinigan Falls in 1912 was about 8,000; in 1918 its population had increased to

FRASER BRACE CO.'S ELECTRIC FURNACE PLANT

14,000. This great increase in population was brought about by the influx of labor from the surrounding territory for the new electrochemical plants constructed since 1915, descriptions of which are given below.

The Northern Aluminum Company is located outside of the electrochemical district but adjacent to the power developments of the Shawinigan Company. This location was chosen on account of the fact that the Aluminum Company utilizes hydraulic power for their

works rather than the electric power of the Shawinigan Company, although a considerable amount of electric power is now purchased by them.

Their works, of an extensive nature, cover about fifteen acres of ground and contain, beside the reduction rooms for the production of aluminium, an ingot room and a rolling mill and a wire-drawing and cabling plant.

The Canada Carbide Company occupies some fifteen acres of land in the industrial district. The company

GRES FALLS

employs some 500 men and manufactures calcium carbide and acetylene gas only and utilizes about 50,000 horsepower.

The Shawinigan Electro Metals Company, whose plant was constructed and put into operation in 1915, produces metallic magnesium in many forms and occupies about five acres with their various processes. They utilize about 2500 hp. in both alternating and direct-current furnaces.

The first plant of the Canadian Electrode Company was constructed in 1915, but since that time two additions to the plant have been made, so that the present capacity is about four times the original capacity. This company manufactures the larger sizes of carbon electrodes for electric furnaces and have an output of about 30 tons per day. The majority of the output is used in Shawinigan Falls, although a considerable tonnage is exported.

The Canadian Electro Products Company manufacture acetic acid, acetaldehyde, paraldehyde, acetone and other similar products from acetylene gas supplied by the Canada Carbide Company. This plant, while primarily constructed for the purpose of supplying acetone and acetic acid to the British Government, has so demonstrated its possibilities that it will continue to be one of the most important industries at Shawinigan Falls when the war is over.

The Prest-o-lite Company constructed in 1917 a plant for compressing acetylene gas for charging Prest-o-lite cylinders. This gas is purchased from the Canada Carbide Company, near whose plant the Prest-o-lite works are located.

Fraser, Brace & Company in 1917 erected a small electric furnace plant of about 1000 hp. for the manufacture of low-phosphorus pig iron. This plant has been very successful and is now being expanded into a considerably larger industry.

In 1917 the Canadian Aloxit Company, a subsidiary of the Carbide Company, erected a plant covering about

fifteen acres of land near the upper end of the electrochemical district. In these works the company utilizes over 20,000 hp. for the production of such electric furnace products as aloxite, carborundum and ferrosilicon.

During the summer of 1918 the requirements of the United States Government for acetic acid led to the establishment of a plant practically duplicating the Canadian Electro Products Company's plant and erected adjacent to the same. This plant, owned by the American Electro Products Company, will be operated by the Canadian Electro Products Company for the production of these products on behalf of the United States Government.

The latest addition to the Shawinigan electrochemical district is the Canadian Ferro-Alloys, Limited, who have constructed a plant near the Canada Carbide Company for the manufacture of ferrosilicon, and utilize some 10,000 hp. for this purpose.

While not electrochemical, two industries in the Shawinigan district are worthy of mention on account of the large amount of power they consume—the Laurentide Company at Grand'Mere utilizing 28,000 hp. for the manufacture of paper and pulp, and the Belgo-Canadian Company at Shawinigan Falls utilizing 18,000 hp. for the same purpose.

#### GENERAL CONDITIONS

The St. Lawrence Valley being tempered by the large mass of water moving from the Great Lakes to the sea has a very steady and pleasant climate. The Shawinigan district has a mean annual temperature of about 50 deg. Fahrenheit, the days being hot in summer but the nights cool. The winters are rather long and cold but the air is dry and great variations in temperature do not take place rapidly, so that to many the winter season is the most enjoyable of all the year.

Shawinigan Falls, like other large, rapidly growing communities, is somewhat hampered at the moment by

THE CANADIAN ELECTRO PRODUCTS CO.

the lack of housing facilities, but houses are being built rapidly and will no doubt keep pace with the increasing population. As an indication of the stability of the labor, it may be noted that a great number of the houses in Shawinigan Falls are owned by the workmen themselves.

There is a Technical Institute in the city having some 150 students and equipped with fine modern laboratories housed in modern buildings. This institute offers a means of education to the younger men in order that they may be better fitted for the industries

existing in the community, and its night courses, which are well attended, aid workmen to become more useful and to become foremen and superintendents.

As the community is quite new, large amounts of land are available for industries, and in general, sites may be found lying between the two railroads so that siding facilities may be had on each. There is no difficulty

LAURENTIDE POWER HOUSE

in obtaining water from the river for industrial purposes, and this water is of such character that it can be used for the majority of industrial works.

The St. Maurice River water is not used for drinking purposes below Shawinigan Falls, and as the salt sea water is met a few miles below Three Rivers, very little, if any, objection can exist to stream pollution from industrial plants.

#### SHAWINIGAN FALLS—THE ELECTROCHEMICAL CENTER OF CANADA

If we examine the reasons which have made Shawinigan Falls such an important electrochemical and in-

BELGO CANADIAN PULP AND PAPER CO.

dustrial center, we find that they may be summarized as follows:

1. Large amount of power actually available at low prices.
2. Cheap labor of a very satisfactory character.
3. Low import rates for ocean-borne materials.
4. Low export freight rates.
5. Reasonable coal costs.
6. Raw materials near at hand.

These influences, which have built up the Shawinigan Falls of today, will be just as active in the future, and as a result the number and size of the electrochemical industries at Shawinigan Falls must increase rapidly. With 100,000 hp. now available as fast as

plants can be erected to utilize it, and with several hundred thousand horsepower yet untouched, the district offers a strategic location for serving the export market, the future basis of business.

At the present time, Shawinigan Falls is one of the few localities in the country where power in quantity can be obtained quickly and cheaply, and where the necessary labor for plant operation can be obtained without excessive importation. With these present advantages and future possibilities, the Shawinigan Falls of the future will doubtless continue to be the electrochemical center of Canada, if not of North America.

Montreal, Canada.

### Doping in Aircraft Works

The annual report of the Chief Inspector of Factories and Workshops for 1917 [Cd. 9108, 3d] contains a special report on "Doping in Aircraft Works" by Mr. S. Smith, Dangerous Trades Inspector, of which the following is an abstract:

During the period in which dopes containing tetrachlorethane were in use 70 cases of toxic jaundice, including 12 deaths, were reported. A standard of ventilation for dope rooms of 30 changes of air per hour was adopted with good results, but in September, 1916, the use of tetrachlorethane was discontinued. The new dopes containing acetone (diethyl ketone), acetone substitutes (impure mixtures of dimethyl ketone, methyl ethyl ketone and higher homologues), and benzol, also the varnishes containing amyl acetate, still gave trouble as regards nauseating smells, and it was found necessary to maintain the same high standard of ventilation as before. Complaints have been received that where the dopes were used intermittently without mechanical ventilation, the effects from the fumes were more noticeable than those from the older poisonous dopes, and this is especially true where large aeroplanes have their fuselage doped in the erecting shops where no system of artificial ventilation can be applied. As far as possible the fuselage components are being doped before assembly, in properly ventilated rooms, as in the case of wings and planes. The use of sprays instead of brushes gives rise to excessive fumes and mists, so that it is still more necessary in such cases to have efficient ventilation.

### Asphodel as a Source of Alcohol

*Aphodelus ramosus*, which contains much starch in its tubers, grows as a common weed (porrazzo) in many parts of Italy; in fact, it has been called "the plague of the Mediterranean." At one time it was cultivated as a source of industrial spirit, but, owing to difficulties in the rectification, the culture was abandoned. If these difficulties could be overcome Italy would be able to considerably increase her home supply of spirit, for it is claimed that every acre of asphodel plants yields 17,350 lb. of roots from which not less than 107 gallons of alcohol could be obtained. When the manufacture of porrazzo was carried out in Algiers the residue from the distillation was used successfully in the production of paper, but it could also be used directly as a cattle food. —(*Annal. d'Ingegn. e d'Archit.*)

# Alcohol in the Arts and Industries

## Government Restrictions Surrounding the Manufacture and Sale of Alcohol Restrict Its Legitimate Uses in Industry—a Brief Review of the Wide Use of Alcohol

By E. H. LESLIE, Ph.D.

**T**WENTY years ago a joint select committee of the Congress of the United States submitted the following statement as part of an official report:

The uses of alcohol other than as a beverage are more largely and widely extended than is supposed. But while the use of alcohol as a beverage is purely voluntary, its employment for all other purposes is legitimate, beneficial, and necessary. No article entering into manufacture or the arts, whether of domestic or foreign production, performs more legitimate or beneficial functions. There is scarcely a manufacturer in the country who does not use alcohol in the production of his goods to a greater or less extent.

Since that statement was made, its force has been many times multiplied. A large number of new uses have been found for the commodity, and a variety of new products have been produced in the manufacture of which alcohol is a necessity. Industrial alcohol is now produced in large and ever-increasing quantities. Table I, taken from the report of the Commissioner of Internal revenue for the fiscal year ending June 30, 1917, shows the rapid increase in the production of industrial alcohol of denatured grades.

TABLE I—PRODUCTION OF DENATURED ALCOHOL

| Fiscal Year | Number of Denaturing Warehouses | U. S. Gallons, 90 to 95 Per Cent Alcohol |
|-------------|---------------------------------|------------------------------------------|
| 1907        | 8                               | 1,780,276.35                             |
| 1908        | 12                              | 3,321,451.73                             |
| 1909        | 12                              | 4,556,418.85                             |
| 1910        | 12                              | 6,079,027.10                             |
| 1911        | 14                              | 6,881,129.86                             |
| 1912        | 14                              | 8,094,515.00                             |
| 1913        | 21                              | 9,831,658.54                             |
| 1914        | 25                              | 10,404,975.59                            |
| 1915        | 23                              | 13,986,468.77                            |
| 1916        | 33                              | 46,679,106.38                            |
| 1917        | 44                              | 55,679,597.63                            |

In addition to the denatured alcohol recorded in this table, a considerable quantity of tax-paid 95 per cent alcohol is consumed for industrial purposes. The quantity of alcohol so used is estimated at 4,200,000 U. S. gallons. The total amount of industrial alcohol consumed in this country therefore approximates 60,-000,000 U. S. gallons.

The entrance of the United States into the war, and the necessity for the conservation of food materials brought about thereby resulted in the passage on August 10, 1917, of an Act of Congress prohibiting the manufacture of beverage alcohol from foods, fruits, food materials and feeds. The importation of beverage alcohol into the United States is also prohibited. Industrial alcohol is therefore at present alone in the field.

### GOVERNMENT REGULATIONS HAMPER INDUSTRY

The war has brought about no radical changes in the industry of industrial alcohol other than to increase the production for war purposes. The Government rules and regulations surrounding the manufacture, sale, and distribution of alcohol still remains

a source of expense and difficulty to the manufacturer and the consumer. The new revenue laws have still further complicated the sale and distribution of domestic alcohol so that today it is difficult if not impossible to purchase a small quantity of the pure commodity for legitimate household use.

The existing regulations governing the manufacture of industrial alcohol are the outgrowth of the moonshine whiskey days. They were designed to curb the illegal activities of numerous small operators. Time has modified these regulations somewhat, but the producers of industrial alcohol today find themselves still surrounded and hindered in the operation of their plants by a host of antiquated rules. The passage of the recent emergency measure prohibiting the manufacture of alcoholic beverages taken in consideration with the probability that this law will continue in force after the war makes the present an appropriate time for a reconsideration of the rules and regulations which hamper the production of industrial alcohol.

### USES OF ALCOHOL IN THE ARTS AND INDUSTRIES

It is scarcely fitting in these days to go into detail on the subject of the relation of the alcohol industry to the war or the uses of alcohol in warfare, though these are matters of considerable interest. It is believed, however, that a brief review of the uses of alcohol in the arts and industries may be of value at this time when at the Fourth National Exhibition of Chemical Industries each and every chemical industry is passing in review before the public eye.

The uses of alcohol may be more or less arbitrarily classified into five groups as follows:

1. Fuel.
2. Raw Material in Chemical Processes.
3. Solvent.
4. General Utility.
5. Miscellaneous.

#### USE OF ALCOHOL AS A FUEL

Alcohol is used for the production of heat, light and power. Since the combustion of alcohol is smokeless and odorless, it is an excellent fuel for use in small stoves, chafing dishes, cigar lighters and a variety of similar devices.

When alcohol is gasified and burned beneath the familiar Welsbach mantle, a clear while light is produced. Burned in this manner a given volume of alcohol will produce over three and one-half times as many candlepower-hours as the same volume of kerosene burned in a good kerosene lamp.

The use of alcohol for power purposes has never been extensive in the United States due in part to the cheap petroleum products available and in a great measure to the reluctance of the Government to remove the restric-

tions which interfere with the development of the art of manufacture of alcohol, curtail production, and increase the expense of operations. In Europe, on the other hand, alcohol in admixture with other liquid fuels has been very extensively employed as a motor fuel.

#### ALCOHOL AS A RAW MATERIAL IN CHEMICAL PROCESSES

*Oxidizing Processes.* The oxidation of alcohol to acetic acid by air in the presence of an enzyme catalyzer has long been a familiar process. It is only recently, however, that the oxidation of alcohol to aldehyde, and the aldehyde to acetic acid, has been brought about by inorganic catalyzers.

Other commodities which may be mentioned as the products of oxidizing processes are chloral hydrate, chloroform, iodoform and fulminate of mercury.

*Dehydrating Processes.* The dehydration of alcohol gives rise to ether or to ethylene according to the manner in which it is carried out. The dehydration with sulphuric acid under carefully regulated conditions produces ether. The dehydration of alcohol to ethylene with aluminium oxide as contact catalyst is a recent war development of considerable interest.

*Esterification.* The production of such esters as ethyl acetate, ethyl formate, and ethyl chloride has been somewhat stimulated by war conditions. Numerous other esters, including ethyl butyrate, oxalate, benzoate, succinate, and aceto-acetate, are also of commercial importance.

*Ethylation.* Alcohol furnishes the ethyl group for the production of the alkylamines, ethyl and diethyl aniline. It is used also in the ethylation of the phenolic group of para-nitro-phenol in the production of acetphenetidin.

#### ALCOHOL AS A SOLVENT OR LIQUID MEDIUM

Alcohol, next to water, is undoubtedly the most important solvent. A brief consideration of its multitudinous uses bears out this fact.

*Solvent for Gums.* Shellac and spirit varnishes are produced by the dissolving of shellac and other gums in alcohol. The alcoholic solution of shellac serves a variety of purposes and is necessary in the manufacture of felt and straw hats, mirrors, brushes, electric lamps, patterns for the foundry, etc.

*Solvent for Soaps.* On account of the fact that the soaps dissolve in alcohol, this substance is used in the manufacture of transparent soap and certain soluble cutting oils. Alcohol is solidified by means of soap. In this form it is used as a fuel for cooking or heating purposes.

*Solvent for Essential Oils.* Alcohol is used both in the manufacture of essential oils and in the preparation of essences. A few typical examples are essences of vanilla, lemon, wintergreen, rose, jasmine, heliotrope and bay.

*Solvent for Nitrocellulose.* While alcohol alone is not a solvent for nitrocellulose, it is used in large quantities mixed with ether in the manufacture of smokeless powders, and collodion. Collodion is consumed in large quantity in the production of artificial leathers, and in smaller quantities in the manufacture of artificial silk. Small amounts of alcohol are used in the preparation of photographic emulsions and in the making of carbon lamp filaments. The manufacture of pyroxylin plastics calls for the use of a considerable quantity of

alcohol. The fact that alcohol in itself is not a good solvent for nitrocellulose is made the basis of the solidification of alcohol by the production of some form of emulsion or colloid of nitrocellulose in alcohol.

*Solvent for Dyes.* Alcohol is used as a solvent in the manufacture of a great many dyestuffs. It is also useful as a medium for the vending of colors to the trade in the form of solutions or pastes. Alcohol soluble colors are used in the making of confectionery and artificial flowers, and in calico printing.

*Solvents for Drugs and Chemicals.* Alcohol is necessary as a solvent in the processes of preparing a variety of drugs and chemicals. A few of these substances which may be mentioned are aloin, arbutin, baptisin, cimfunin, coumarin, hydrastis, inisin, mandrake, phenolphthalein, phytolaccin, strychnine, tannic acid and viburnin.

*Solvents for Use in the Preparation of Tinctures.* The alcoholic solutions of numerous drugs and chemicals are placed on the market as tinctures. A few typical examples are tinctures of aconite, arnica, cantharides, digitalis, iodine, and nux-vomica.

*Solvent in Crystallization Processes.* A large number of substances are recrystallized from alcohol, among which may be mentioned aconite, beta-naphthol, beta-naphthol benzoate, guaiacol, guaiacol carbonate, monobromated camphor, ortho-toluol sulphamide, phenyl salicylate, and terpin hydrate. In the case of other substances, such as trinitrotoluol (TNT), crystals are sometimes washed with alcohol to remove impurities.

*Alcohol as a Cleaner or Cleanser.* Oil and shellac are removed from metal parts by means of alcohol in the process of manufacture of various articles such as cutlery, jewelry and watches, silverware, bronze and art metal work, and special glassware such as thermometer and barometer tubes.

*Solvent for Oils and Waxes.* Alcohol is used in the manufacture of celery oil, shoe polishes, and paint and varnish removers. It is used in the refining of mineral oils for the production of the highly refined medicinal oils. It is sometimes used in the purification of rubber to dissolve foreign gum and waxes.

*Alcohol as a Diluent or Thinning Solvent.* A number of preparations such as airplane wing dopes, metal lacquers, enamels, polishes, lotions, and linaments contain alcohol as a diluent.

#### ALCOHOL AS A LIQUID OF GENERAL UTILITY

In the hospital, the chemical laboratory and the home, alcohol is a liquid medium of general utility. In the hospital it serves as an antiseptic and as an abluion. In addition to these purposes, it is used extensively in the home as a fuel and cleaner. Its indispensability in the laboratory is too well known to every chemist to need elaboration.

#### MISCELLANEOUS USES OF ALCOHOL

Alcohol finds application for a variety of purposes which are difficult to classify. It serves as a preservative for specimens in biological museums. Many proprietary medicines also contain a certain proportion of alcohol added to preserve other components of the mixture.

The addition of alcohol to the water in automobile radiators, hydraulic jacks and presses in the winter

time prevents freezing. This has proved of extreme importance in the war. Water is frequently scarce near the battlefield, and it is highly desirable to be able to avoid the draining of the water from radiators at night. An economy of gasoline also has been effected through lack of the necessity of keeping the engine running when a car was idle for a short time.

Alcohol is used to remove the carbon from automobile engines or other gas or gasoline engine cylinders. The "carbon" is an accumulation of siliceous dust, carbon and heavy tar and oil. The solvent effect of the alcohol on the oils and tars is responsible for the removal of the carbon.

Alcohol is used as an antiseptic. Solutions of such substances as resorcin or beta-naphthol in alcohol are exceedingly valuable in this connection.

Alcohol serves as a reaction medium in the manufacture of a number of substances among which may be mentioned santonine benzoic acid and sodium benzoate.

The small solubility of certain substances in alcohol is responsible for the use of alcohol in their processes of manufacture. Such substances are inulin and glycerophosphates.

#### CONCLUSION

It has been possible in the foregoing paragraphs only to mention some of the many uses of alcohol in the arts and industries, but this brief enumeration is sufficient to illustrate the ramifications of this substance into manufacture in general. Its importance at present cannot be overestimated. Its future possibilities are limited only by the regulations with which its use is circumscribed.

U. S. Industrial Alcohol Co.,  
New York City.

### Utilizing Waste Sulphite Liquors

In 1906 letters patent were granted to Jacob S. Robeson for a process to neutralize and concentrate *in vacuo* the waste liquors of sulphite pulp mills. The inventor and his associates made the proposition to a pulp mill that was having trouble with stream pollution, to put the offending waste to use and a little test plant was built with a view to producing by this means an adhesive to make sand cores for hollow castings. How much of the offending liquor could thus be disposed of was a question, and it stands to reason that the amount, during the formative period, was not large. In the meantime the proprietary company has developed so that it now has two large evaporating plants which substantially consume and thus dispose of the waste liquor output of two large sulphite mills, one at Au Sable Forks, N. Y., and the other at Covington, Va.

The feature of general interest which we think worthy of emphasis is that in the instances of these two mills, the waste liquor nuisance is said to be practically eliminated. The process, roughly, consists in neutralizing the liquor and evaporating it to a thick syrup or to dryness under reduced pressure. Of course there are stratagems and refinements in the process. The ligneous spruce product is sold under the trade name of glutrin. It is, in substance, the sulphonated lignins neutralized with lime and magnesia, with other bases substituted or the lime removed for special purposes by processes patented and controlled by the company.

As a core binder it did well from the start and its use in this respect has already reached large proportions. But even if all the foundries in the world should use it, a few pulp mills could supply the entire demand. Later research, however, proved that the gum had an unusual affinity for clay and the manufacturers set out to introduce the product as a road binder.

Portland cement with sharp sand in volume 1 to 3 breaks approximately at 200 to 230 lb. Glutrin with sharp sand mixed with 15 per cent of clay shows the same tensile strength in volume of 1 to 25.

Other uses are coming to the fore, but none with the possibilities of road binding except, perhaps, as an adhesive for briquetting. Much less glutrin is needed than pitch for this purpose and in this respect it is promising, owing to its cheapness as well as its effectiveness. Last winter during the coal famine it was found useful to bind coal dust for boiler purposes without going through the process of briquetting. Coal dust, which was all that was obtainable by some landlords, was dumped upon the boiler room floor, glutrin was poured upon it which immediately bound it, and then it was fed wet into the fire boxes of the boilers. Several large buildings were kept warm by this means which otherwise would have been closed by the cold. When glutrin is submitted to the high temperature of the fire under the boilers it burns completely.

Still another use after it has undergone purification is for finishing leather in the tanning industry. It contains 25 per cent of tanning materials, which is significant. This application is also increasing.

The material itself is soluble in water but it can be made practically waterproof. If two pieces of paper are held together by an exceedingly thin film of glutrin, they become impervious to oil and grease, and it is suggested that cartons made of paper with glutrin sandwiched in between the sheets, would make good containers for oily substances.

Again there are indications of its use in the textile industry, although no method of bleaching has thus far been devised.

More important than the introduction of a new technical material is the avoidance of sulphite pulp waste liquor. We continue to talk a great deal about this nuisance but it continues to flow into our most beautiful streams and to kill fish merely as one of its many vices. Evaporated, it has its uses, but not enough. What interests us especially is that some application be discovered for evaporated sulphite waste liquor, whether prepared by this process or any other, so that one of the greatest of all sources of stream pollution may become a thing of the past. If a large, general use for the product could be discovered we should soon see a treating establishment attached to every pulp mill and a source of serious offense turned into an asset. The chemist who solves this problem will probably reap a fortune, but he will also be justly entitled to a medal from Congress, and the day of its accomplishment may not be so far away, either.

Artificial Honey is reported as being prepared in Germany. The hydroxide or other suitable compound of iron is added to sugar during inversion whereby salts of iron are produced with the acid used for inversion and saccharates of iron with the sugar.

# Organic Synthesis and the duPont Company

Evolution and Growth of a Varied Organic Chemical Industry—Introduction of Nitro Explosives Brought About First Advance—American Chemical Manufacturers Must Blaze New Trails and Engage in Thorough Research

By C. L. REESE AND C. M. STINE

**S**YNTHETIC organic chemistry has been a factor of such great importance in the development of the wide variety of the du Pont Company's products that it is difficult to pick out of the finished products marketed by this company any one product in the development of which the organic synthetic chemist has not had a part. Evolution and growth are not necessarily simultaneous processes. The former represents increasing complexity and better adaptation to commercial requirements and is more important than mere growth, consisting of expansion without added differentiation. It is safe to say that the development of the du Pont company has been characterized by both. During the very early years of the life of the company, when its activity consisted almost solely in the manufacture of black powder, no applied organic chemistry was involved, but this situation was altered with the introduction of nitroglycerin and nitrocellulose explosives. The next great advance came with the introduction of the benzol high explosives which led quite naturally into the field of coal-tar products, in general comprehending intermediate and dyes as well as numerous other products in adjacent domains of manufacture, all logically associated with each other.

## STUDY OF SYNTHETIC GLYCERINE.

Dynamite contains as one of its most essential constituents nitroglycerine or similar nitric ethers, together with one or more organic compounds of a similar nature, added for the sake of introducing some special property or properties in the finished product. The manufacture of nitroglycerine itself has meant for this company not merely the nitration of glycerine but also the study of various methods for synthesizing glycerine. Coincident with the study of synthetic glycerine the study of other nitric ethers of very similar properties has been under way for years and has resulted in the synthesis of certain nitrated products, true nitrates—not nitro substitution products—which have served to replace varying quantities of nitroglycerine and at the same time to give the dynamites certain very valuable properties not conferred upon them by the use of nitroglycerine alone.

Then too there is the field covered by the nitro aromatic compounds which are used not only in admixture with nitroglycerine and other nitrated alcohols of similar constitution, but some of which are themselves employed as explosives. The manufacture of nitro compounds derived from benzene, toluene, xylene, phenol, cresol etc., has often involved not merely the study of the action of nitric acid upon these organic compounds but in some cases has involved a study of methods for the manufacture of the compounds them-

selves. Toluol has been produced on a commercial scale by the du Pont company for some years past, and, of course, synthetic phenol and the synthesis of picric acid through chlorbenzol instead of by the nitration of phenol are operations which at once occur to every chemist who may chance to read this article.

It is scarcely necessary to say that such compounds as tetranitromethylaniline, the "tetryl" of commerce, have been manufactured by the du Pont company for some years and that the manufacture was worked out as a going proposition before the great war had started. The nitration of benzol, with the production of mononitrobenzol and from this of aniline, had led to the manufacture of diphenylamine and dimethylaniline.

## EVOLUTION OF NEW EXPLOSIVES

The development of new explosives so necessary to enable the du Pont company to develop its great explosives business has, of course, led to the study of a very wide field of organic compounds which for one reason or another were believed to be worthy of investigation for the sake of determining their possible suitability in this connection. A number of very useful new explosives have been developed and some of these compounds will no doubt prove a fruitful source of interesting investigation when a study is made of their properties other than explosive.

The manufacture of smokeless powder involves a very expert knowledge of the nitration of cellulose and the conduct of various nitrates of cellulose in different solvent media. This business very naturally went hand in hand with the development of such products as lacquers, pyroxylin solutions and leather substitutes. These lines of business, calling for colors, involved either the purchase of dyes, pigments and lakes from outside sources or the manufacture of these products by the company. The company preferred to engage in the manufacture of these products for itself, because of the close relation to its business as a whole as well as because it is one of the largest manufacturers of heavy chemicals in the world.

The preparation of the nitro aromatic compounds already referred to is so closely akin to the preparation of some of the raw materials used in the manufacture of dyes that it was scarcely a step for this company to launch out into a very comprehensive manufacture of intermediates used largely for dyestuffs, as well as in a more limited way for pharmaceuticals. When one enters the wide and fascinating field of the chemistry of dyes and intermediates, the activities of the organic chemist at once become of the first importance. This is so well known that it is scarcely necessary to do more than mention in passing that hundreds of chemists are

engaged in the manufacture of various organic compounds used for explosives and dyes.

#### DIFFICULTIES OF ORGANIC SYNTHESIS

In a surprisingly large number of cases chemical investigation of synthetic processes has resulted in the discovery of improved methods, differing widely from those previously employed. In all cases the study of synthetic methods has resulted in less radical though no less important changes in the methods themselves. Nothing sounds easier than the preparation of some well known organic compound such as diphenylamine. A cursory examination of the literature furnishes a description of various methods of preparing this material, but like all other organic reactions it requires careful control if satisfactory results are to be obtained. It is influenced by conditions which are nowhere mentioned in the literature because they can be ignored in the small scale preparation of the material. Furthermore, the chemical manufacturer who produces this material in large tonnages is not given to publicity in regard to details which determine the success of his plant. Every stage and every detail of preparation must be subjected to the closest scrutiny. Wholesale production of course requires more accurate regulation than does laboratory preparation. When a pound of the material is prepared the occurrence of small amounts of by-products is ignored, except in so far as these by-products and residues merit study because of the light which such a study may throw upon the reaction. But the large scale manufacture may fail entirely because of the accumulative catalytic effect of small amounts of by-products developed in the reaction and adhering to the interior of the apparatus from one run to the next, even though the bulk of the product is removed from the apparatus after each charge.

#### VARIED PROBLEMS ATTACKED BY DU PONT CHEMISTS

Perhaps it would be interesting to enumerate a few of the many and varied problems which the organic chemist has turned his attention to at one time or another in the synthetic laboratories of the du Pont company. The company is manufacturing brushes for "my lady's toilet table." The handles and backs of these brushes call, first of all, for cotton of a particular grade and the purification of this cotton. Next, this specially purified cotton, the properties of which have been studied from every standpoint in so far as the nature of the impurities present in the cotton and the methods followed in their removal may affect the desired properties of the finished article, is subjected to the action of a mixture of nitric and sulphuric acid, and the nitric ether of cellulose thus obtained is ready for purification. Here again the most thorough-going and far-reaching study is made of the effect of various impurities in the nitrocellulose and the effect of the different methods used for removing these impurities upon the physical and chemical properties of the finished toilet articles. Perhaps the finished toilet article instead of being white or cream colored is to be tinted or is to be inlaid with some colored design. It is necessary to study the various coloring matters available, with a view to selecting such dyes as may be soluble in the solvents employed in working up the nitrated cellulose, and at the same time dyes which will show

the necessary fastness to light and the necessary stability so far as the action of the colloid or of the air is concerned. Now the brush is complete save for the insertion of the bristles. Here a new problem presents itself—a shortage of the natural bristles which used to be imported before the war. It becomes necessary to attempt to prepare artificial bristles. At first glance this seems a simple proposition, but a naturally produced bristle has many unique properties and it becomes necessary to make a most painstaking investigation of the nature of these properties which give the natural bristle its character in order that in the duplication of this bristle it may be possible to decide when a synthetic article of the proper degree of excellence has been prepared.

#### PRODUCTION OF ARTIFICIAL LEATHER.

Closely related with the production of articles of "pyralin" is the production of the class of goods known as artificial leather or fabrikoid. The coating of suitable fabrics of various weaves and tints with pyroxylin solutions and the subsequent fabrication of these coated goods to a leather-like finish has involved the attention of many chemists, and many interesting discoveries have been made in this connection. The manufacture of fabrikoid well illustrates the variety of chemical processes and products which may be involved in the fabrication of single class of goods. Suitable purified cotton, acids, alkalies, solvents, oils, dyes in wide variety of shade and chemical properties, pigments, etc, enter into the manufacture of artificial leather.

It is worth pointing out in this connection that the field of the organic chemist is by no means merely the imitation of nature's products, but oftener than not the problem involved is the actual building up in the chemical laboratory of the identical product which nature herself has cunningly synthesized in the organism of the plant or animal, as the case may be.

#### SYNTHETIC INDIGO ILLUSTRATES PROBLEM OF LARGE-SCALE PRODUCTION

The manufacture of indigo well illustrates the nature of certain problems which arise if the chemical manufacturer attempts to produce on a large scale even such a product as this which has been produced for some years on a large scale abroad. If the chemical turns to the literature he finds many methods for the preparation of this material, but it is a question not merely of the selection of a method which will produce indigo but of the selection of that method which will best produce indigo of the highest quality and in the most economical way, from certain raw materials which are available because of the du Pont company's activities along other lines. Having selected the method which is to be followed, the next question is the design of the most suitable apparatus for carrying out this method on a very large scale. Without going into wearisome detail, it suffices to say that all of these phases of the problem have been studied and successfully solved and an indigo produced which is much purer than that which is obtained by the extraction of this dye-stuff from its naturally occurring sources.

The embarkation of this company upon the great field of related industries comprehended under the caption "duPont American Industries" will no doubt mean

a wonderful stride forward for the American chemical industry. The logical course is to build an industry which is not merely concerned with chemical products in the narrower sense but with all the logically related forms of the industry. As in the past, success in organic synthesis as a commercial asset can only come to mean what it should if it is properly associated with evolution of the whole industrial organism of which it is a part. We are confident that new processes or distinct improvements over foreign methods of manufacture will characterize the activities of this concern. This is logically to be expected because the chemical manufacturers in the United States start with a clean slate, unhampered by tradition, unencumbered by equipment which may have grown more or less obsolete but which it would be too expensive to abandon. It is necessary above all things that the American manufacturer shall not merely attempt to follow the well beaten paths, but that his activities be controlled by a thorough and painstaking application to his manufacturing problems of the results from the laboratory of the thoroughly trained and skillful synthetic organic chemist.

Wilmington, Del.

### Prices of Sulphuric and Nitric Acids

The War Industries Board announced on September 26 that, subject to the President's approval, the following maximum prices were agreed upon at a meeting between manufacturers of sulphuric and nitric acids and the price fixing committee. These prices are to remain in effect for the remainder of the year:

|                      |             |          |
|----------------------|-------------|----------|
| Sulphuric Acid ..... | 60 deg. Bé  | 2000 lb. |
| .....                | 66 deg. Bé  | \$16     |
| .....                | 20 per cent | \$25     |
| Oleum .....          |             | 28       |

All acids below 66 deg. Bé. are to be evaluated on a \$16 basis and above 66 deg. Bé., on a \$25 basis. One-half of one per cent additional charges are to be made for carload lots of carboys, and three-fourths per cent for less quantities. One-quarter of one per cent will be charged for steel drums.

|                   |            |          |
|-------------------|------------|----------|
| Nitric Acid ..... | 42 deg. Bé | 2000 lb. |
|                   |            | \$170.00 |

One-fourth of one per cent extra charges are made for drums. There shall be no extra fee for mixing charges of mixed nitrating acids, the prices of which are figured on the acid contents.

### Two Great Drives, One of Them Here

Two great drives are to release the world from the hardships of war and preserve mankind from the horrors of autocratic rule. One is along the Western Front in France, Flanders and Lorraine; the other is in the United States.

American soldiers are bearing a brave and splendid part in the military drive "Over There." The American people over here must work as well for the success of the Fourth Liberty Loan drive.

Upon the success of the loan depends the maintenance of the striking force of our troops.

It may be hard for many of us to spare money at this time, even though it is to be returned to us with interest; but it would be still harder for us to think of having failed to do our part if the loan should fail.

## Manufacture of Glycols

BY HAROLD HIBBERT

Director Research and Technical Division,  
Ralph L. Fuller & Co., Inc.

IN a preceding article on "Industrial Developments Relating to the Manufacture of Acetic Acid and Acetone," attention was drawn to the scarcity of acetone occasioned by the increased production of cordite, and of the steps taken to meet this deficiency. Regarding the other two constituents of this explosive, namely nitrocellulose and nitroglycerine, thanks to our abundant natural resources little or no difficulty was experienced in increasing the production of nitrocellulose, but the amount of cordite capable of being produced at the present time is limited by the amount of nitroglycerine available.

As is well known, nitroglycerine is obtained by treating glycerine with a mixture of nitric and sulphuric acids. The glycerine itself is obtained by heating vegetable oils, such as palm oil, cottonseed oil, etc., on the one hand, or animal fats on the other, with caustic alkalis or other saponifying agents producing in this way glycerine and soap. Animal fats form an indispensable, staple article of diet and the same remark now applies to vegetable oils, since from these, by the so-called process of hydrogenation (consisting in treating them with hydrogen), these bodies are converted into butter substitutes and so serve to replace animal butter and animal fats.

It thus becomes an economic problem as to how far the manufacture of glycerine may be permitted without interfering with the use of raw materials for domestic consumption. An idea of the amount of glycerine used in this country prior to the war, may be obtained when it is stated that some 20,000 tons of this material was employed annually in the manufacture of nitroglycerine, while another 7000 tons was used in the manufacture of tobacco. The other uses to which glycerine was put amounted to probably around 3000 tons, so that the total annual consumption in this country prior to the war did not fall far short of sixty million pounds.

Numerous attempts to produce glycerine synthetically from other cheap available raw materials such as sugar, petroleum, etc., have been made, but so far without success. It is a well known fact that in the fermentation of wine, a considerable amount of glycerine is formed from the sugars present, but all attempts to identify the organism and to imitate the process commercially, have so far proved failures. As far as can be judged, there would seem to be comparatively little outlook at present for a successful commercial synthesis of glycerine from known available materials. At the same time, it is not possible to increase the supply of glycerine without in turn diminishing the supply of foodstuffs.

During the last six or seven years the writer has devoted a considerable amount of time to experimenting on this subject, and now believes that in a certain class of products known as glycols, which are closely related on the one hand to ordinary alcohol, and on the other to glycerine, a solution of this problem has been found.

If alcohol is passed over certain contact materials, such for instance as oxide of aluminium, at an elevated temperature, it undergoes a chemical decomposition with the formation of steam and a combustible gas known

as ethylene. This gas is very reactive and combines readily with chlorine forming a product known as "Dutch Liquid," or to give it its chemical name, dichloroethane. The first name was given to the compound due to the fact that it was first discovered by some Dutch chemists in 1795.

When this dichloroethane is heated with water and alkaline carbonates in a closed vessel, a chemical decom-

position takes place resulting in the formation of common salt and a chemical product known as ethylene glycol.

This product can also be obtained by cracking petroleum by passing the vapors through an iron tube heated to about 650 deg. C., mixing the gases thus obtained with chlorine, and after purifying the product so obtained by distillation, subjecting the distillates to the action of alkaline carbonates in a closed vessel. By such a process it is much more difficult to obtain a pure chemical product, but the mixture of glycols thus prepared possesses many valuable properties.

The products so prepared are liquids of a somewhat less viscous character than glycerine, and possess the power of attracting and retaining moisture. In addition they also yield valuable explosives when treated with a mixture of nitric and sulphuric acids. Some of these were tested in Germany prior to the war and were reported on very favorably by certain large explosive manufacturers. While nitroglycerine possesses many advantages over other explosives, it also has several serious drawbacks. One of these is the fact that while it is a liquid at room temperature, it nevertheless freezes during cold weather and its use in this condition is attended with many difficulties and danger. Although many attempts have been made to overcome this, it cannot be said that the matter has, up to the present time, been satisfactorily solved.

This is due to the peculiar, inherent properties possessed by the frozen material. It was proved some years ago in experiments carried out by the writer that when

freshly prepared nitroglycerine explosives are exposed to a low temperature, they freeze, and in this condition the material represents an unstable product, since under the influence of small physical changes it undergoes instant transformation, while in the solid state into a second totally different crystalline modification, with evolution of a considerable amount of heat.<sup>2</sup> The physical factors involved in such a change may be visualized in a very crude manner by comparing them with the stresses and strains necessary, for instance, to change the contour of, say a rectangular cardboard box instantly into one of more complex form, *e. g.*, hexagonal shape.

In Figs. 1 and 2, 3 and 4, are shown actual photomicrographs of the two solid form of nitroglycerine crystals. Figs. 1 and 2 illustrate the unstable, labile form, while 3 and 4 represent the second or stable modification. Bearing in mind the illustration just quoted of the "cardboard box," it can readily be imagined that when a sensitive product, such as nitroglycerine represents, is transformed instantly from one solid crystalline structure into a second, totally different crystalline form, there must be considerable molecular stresses and strains produced, so that at this particular moment the product is super-sensitive to impact and other physical factors. It is believed that this explanation probably furnishes a solution of the numerous unexplained explosions which have taken place in handling nitroglycerine explosives.

In the case of the nitroglycerols, these freeze only at temperatures much lower than in the case of nitroglycerine and as there is no possibility of the formation of an intermediate, unstable, crystalline solid it follows that such explosives are naturally much less dangerous to handle and may therefore be expected to prove of

Fig. 1.  
NITROGLYCERINE IN UNSTABLE, MORE SENSITIVE FORM

Fig. 2.

Fig. 3.  
NITROGLYCERINE IN STABLE, LESS SENSITIVE FORM

Fig. 4.

especial value for mining and blasting operations, carried out at low temperatures. It is, in fact, this "safety first" feature which points to the possibility

<sup>2</sup>Zeltgesamte Schiess u. Sprengstoffwesen, Vol. IX, pp. 83-126, and 273, 1914.

of the nitroglycol displacing in future the less satisfactory nitroglycerine explosives.

Furthermore, as regards its use as a constituent of cordite, it is necessary, as stated in the writer's previous communication, in order to bring about an intimate compounding of it with the nitrocellulose, to employ a solvent, which in this case is acetone. This necessitates considerable care and expense in manufacturing, as the value of the explosive is naturally dependent on the absence in the finished product of all traces of the solvent.

We are informed by Mr. Arthur Hough, formerly of the Canadian Explosives, Limited, that extensive experiments carried out by him with nitroglycols on the semi-industrial and industrial scale show that when compounded with nitrocellulose (no solvent being necessary), a valuable new type of explosive is obtained, possessing characteristic properties which indicate that it should be capable of finding a wide outlet both as a war material and for peaceful purposes. With regard to cordite, it is a well known fact that due to the high local temperature produced in the ignition of the charge in big naval or coast defense guns, considerable erosion is produced in the barrel, so that the life of such a gun is limited. This erosive action, will, it is considered be found to be much less pronounced with explosives derived from nitroglycols than from nitroglycerine.

Another new type of explosive, in addition to those described above, has been discovered by the writer. It has been found that sugar is readily dissolved on warming with the glycol and that if such a solution is then treated with a mixture of nitric and sulphuric acids, not only is the glycol itself converted into an explosive body, but the sugar also yields a nitrated product and the combination of the two thus formed is found to possess many valuable properties not associated with any present known types of explosive. There would seem to be solid ground for the belief that such a product should find an extensive application in various branches of the industry, such as mining, blasting, excavating, etc. In view of the fact that one of the principal constituents, namely, sugar is a material available in practically unlimited quantity and at a low cost, it is anticipated that the cost of production of these new products will be materially lower than that of similar bodies derived from nitroglycerine, thus insuring them a very wide outlet.

The glycols themselves have been found to possess many other valuable properties, serving to indicate that they should find a wide application in the field of industry and commerce, so it may be anticipated that in the future the use of glycols will largely displace that of glycerine.

Thus for instance, with regard to the use of glycerine for moistening tobacco, it is known that the combustion of glycerine gives rise to the formation of a poisonous product known chemically as acrolein, and it is assumed that it is the inhalation of this product during smoking that produces in the case of persons susceptible toward such bodies, various types of disorder in the mouth and throat. The chemical composition of the glycols is such that it is impossible for acrolein to be produced when employed for such purposes.

The glycols possess, if anything, a superior attractive power toward water, so that their moisture-retain-

ing properties are even more pronounced than in the case of glycerine.

It is this so-called hygroscopic property (that is, the ability to absorb and retain water) that would seem to make glycols such valuable products for use in the pharmaceutical and allied industries, as for instance in the manufacture of salves, ointments, dressings, etc.

It is also confidently anticipated that the glycols will, on account of their much lower volatility and their affinity for water, prove capable of being used with success to replace alcohol in automobile radiators in order to prevent the water from freezing.

The manufacture of glycols and their industrial applications is a subject which, as stated above, has occupied the writer's attention for a considerable number of years, and due to the fortunate patent protection already available, it is confidently anticipated that rapid strides will now be made in the development of this industry.

The Government has undertaken to investigate the properties of these materials for war purposes, having had the free use of the patents in connection with the same placed at its disposal by the writer for the duration of the war.

There are already in existence certain large factories which are capable of providing raw materials for these products on an immense scale after the conclusion of peace and there is no doubt that with the development of this field a big advance in the true conservation of foodstuffs will have been attained.

New York City.

### Bauxite Deposits in Guiana

Sir Walter Egerton, in his address before the Royal Society of Arts, stated that in 1897 and again in 1910 Professor Harrison reported that extensive deposits of high grade bauxite were located in British Guiana. This discovery was not fully appreciated until five years ago, when the Northern Aluminium Company of America applied for leases of areas containing such deposits. The British Government stipulated that any company working this bauxite must be under its control. After long negotiation, an American company was formed to meet these requirements, and the first cargoes of bauxite were but recently mined and shipped from the colony.

This company has acquired large areas of land from private owners and leases of considerable extent of crown land in the vicinity of Wismar, at the head of navigation of the Demerara River, near the terminus of the little railway connecting the Demerara and Essequibo rivers. Ships with less than 16-foot draft can reach the mines 60 miles above Georgetown.

The bauxite deposits have recently been traced almost from the Venezuelan boundary across the colony to the border of Dutch Guiana. Further deposits have been located in Dutch and French Guiana and it is now thought that this northern strip of South America contains the most extensive deposits of aluminium ore in the world accessible to ocean transportation. The geological formation of bauxite is similar to our secondary fall-line clays, being deposited at the pre-coastal line.

In the United States pockets of bauxite are being worked in Alabama, Georgia and Arkansas, but the shallow depth of the usual bauxite formations makes the Guiana deposits extremely important.

# Micro-Organisms in Plant Chemistry and Nitrogen Fixation

## An Account of the Development and Application of Micro-Organisms Useful to Plant Growth— Fixation of Nitrogen in the Soil

By ELLWOOD HENDRICK

A FEW miles to the west of Hackettstown, N. J., there are some three or four thousand acres of meadow-peat or muck which was formerly covered by a swamp. Underlying it is usually a thin layer of sand which in turn rests upon blue clay. The depth of the greatest part of the muck is from four to six feet, although in places it is but 18 inches; occasionally, it goes down as far as twelve or fifteen feet. Where it extends below the water table there is usually found a layer of fibrous peat above the sand, but there is not much fibrous peat in this district, which is known as Great Meadows or Bog Egypt.

The muck is, in effect, humus, and its use is for fertilizer. But before we begin to consider the technical generalities which follow, let us bear in mind that humus is partly decayed organic matter; that it is the decayed remains of former generations of plant and animal life, on its way to become coal, and beyond the peat stage. Its value is influenced by the kind of organic matter from which it originates, and the state of its decay. Much of its value is due to its nitrogen content, and in this respect, if its origin were cellulose, it would be nil; if it were clover it would be considerable and if derived from the decayed carcasses of animals, it would be higher still. Indeed, the index of its nitrogen value is its pre-geologic history.

But apart from this, humus has other qualities which cause it to function in the support of plant life. It acts as a flocculent in clay and as a binder in sand which might offer at the start a pretty thesis in colloid chemistry. It retains moisture like a sponge, which is another good subject for original work. It supplies, according to its content, nitrogen, phosphorus, potash, lime, iron, manganese etc. for the nourishment of plants, and it is the natural habitat and food of beneficial soil micro-organisms.

### NEUTRALIZING VALUE OF LIME

The New Jersey deposit has the advantage of constituting the drainage area of the surrounding limestone hills whereby enough carbonate of lime is brought down almost to neutralize the humic acids. Still another advantage is that 30 years ago the swamp was completely drained and then practically abandoned. There was lacking the proper understanding of the value of the humus and the development of engineering as well as chemical and biological methods of treatment which later study has supplied. The great value of this preliminary draining in increasing the bacterial life will shortly appear.

For the past twelve years Mr. John N. Hoff of New York and his associates have been engaged in the development of the industry in New Jersey, and later they

have extended their activities to certain other rich deposits in Florida. While the undertaking is to be classed as a fertilizer proposition, it differs materially from fertilizer manufacture and materials as generally understood in chemical engineering.

We often hear fertilizer discussed as though it had to do with abstract problems in chemistry. We know of no other subject to which the popular mind has attributed more than its rightful share of this science. We do not mean to say that the chemistry of fertilizers has been adequately studied; on the contrary, it seems as though, to mention but one of many features, that the great field of protective colloids in the soil holds all sorts of treasures that have not yet been uncovered.

THE DIGGER AT WORK

What has often been forgotten is that agriculture is a profession within the domain of plant physiology rather than of chemistry. In what follows we shall observe that a balanced conception of fertilizers has ruled and that its biological aspect has received its proportionate attention.

### MICRO-ORGANISMS REQUIRE FREE OXYGEN

Operations are carried on under a corporation known as the Alphano Humus Co. and research is prosecuted in various directions under the auspices of that company. We are informed that there are promising indications that it may become possible by simple treatment to bring the humus into a condition whereby the solubility of its nitrogenous bodies may be under almost complete control. The value of such an achievement needs no comment.

The micro-organisms which are most useful to plant life in the soil are of an aerobic nature; that is, they require free oxygen for their development and growth. They do not thrive under water. Therefore the first step in the development of such bogs is to drain. Here we

may note the value of the operations at Great Meadows thirty years ago, because the zymotic growth begins immediately after the water has been removed. Here also we may note again the value of the surrounding hills, for whenever humus is found to be acid it must be limed. As the bacterial life proceeds, some of the carbon in the organic matter goes off as  $\text{CO}_2$ , while under the action of the nitrogen fixers the nitrogen con-

TRANSPORTING HUMUS FROM FIELD TO WORKS

tent is increased. It is interesting to note that there are nitrifying organisms (actinomycetes) which are closely allied to yeast plants as well as moulds or fungi which seem to be especially active, besides the bacteria proper.

The next step is to grow crops under which the condition of the humus improves through aëration, while the crops themselves are record breakers. Onions may be raised to the extent of 1000 bushels to the acre, while 800 bushels may be obtained with ease. Cabbage grows with great vigor and heads up as solid as a German professor when he discusses the cause of the war. Potatoes produce 400 to 500 bushels to the acre while lettuce runs over 1000 boxes to the same area. A box contains 24 large, solid heads. Celery is equally prolific; there are usually over 200 crates to the acre and it takes 120 such crates to fill an ordinary freight car. If all of this district were under diligent cultivation it would effect a material contribution to the metropolitan food supply. Cultivation also eliminates the seeds of weeds.

#### MINING THE HUMUS

When it is determined to mine the humus after cropping, a temporary narrow gage railroad track is laid upon the surface. Then parallel with the track, at a distance of about 150 feet from it, operations are begun with a specially constructed digger, driven by electricity, with a trailing wire. This proceeds very slowly, digging a trench to any depth up to six feet by means of buckets, scattering the humus upon the surface between the trench and the railroad. Surface water is removed from the trenches by rotary pumps. The surface is then harrowed several times each with tractor-drawn harrows of three types, viz., disc, acme (or corkscrew) and spike-tooth, to a depth of two to three inches. After drying in the sun for a day or more it is pushed to a

depth of about two inches over to the railroad track by means of an electrically-driven scraper. We then have a windrow or ridge of sun-dried humus ready for loading. The water content has been reduced from around 80 per cent to between 50 and 60 per cent. A third electrically-driven apparatus loads it upon dump cars on the track. The digger, scraper and loader are all specially designed and built for the purpose and they do their work exceedingly well. The railway carries it to the factory where the humus is piled in great heaps of 25,000 to 50,000 tons. These are, in effect, composting heaps, and the longer they remain the richer the zymotic life of the humus grows. The moisture content does not increase.

#### MECHANICAL PREPARATION BY DRYING AND SCREENING

Three separate products are made from this material. The simplest and cheapest is called "humus tankage." To make it, the humus is run through a rotary, direct-heat dryer, revolving six times a minute. It requires about fifteen minutes for the humus to run through. A very simple test provides against over-heating: as soon as it burns, the smell of ammonia is noticeable and the fires are slowed down. From the dryer the humus is passed through screens and the tailings are ground and then also screened, so that the finished product is in a pulverulent condition. The process is carried on under laboratory control. The humus now contains 10 per cent water, 3.25 to 3.50 per cent  $\text{NH}_3$ , 0.3 per cent  $\text{K}_2\text{O}$ , 0.4 per cent  $\text{P}_2\text{O}_5$ , and about 8 per cent lime, with 80 per cent and over of organic matter. The bacterial count is light, owing to the high temperature drying.

This is, itself, a low-grade nitrogen fertilizer, but its particular use is as a fertilizer ingredient. In this

ROTARY DRYERS

connection it is better than dried blood because it absorbs water more readily and keeps the mineral content in a more pulverized condition. The advantage of having some of the nitrogen in a mixed fertilizer in organic form is well known. If its fixed nitrogen is made up of ammonium sulphate, ammonium nitrate and nitrogen organic matter, the solubility is more gradual and the loss through seepage is less than if all the nitrogenous is in an inorganic form. If used separately, the effective fertilizer value of nitrogen humus is claimed to be about three times that of  $\text{NaNO}_3$ .

The second product is called "prepared humus" and is made from the same basic material, but run through the dryers with a lighter fire so that the water content is brought down to 18 to 25 per cent. This is as low as it can be economically obtained without destroying

HEAPS OF HUMUS AT LEFT AND STABLE MANURE AT RIGHT HAVING THE SAME FERTILIZER VALUE
